Lecture 10 Transformation of the Boundary-Value Problem #6.7

According to Lambert's Theorem

$$\sqrt{\mu}(t_2 - t_1) = F(a, r_1 + r_2, c)$$

the orbit of the boundary-value problem can be transformed to a rectilinear orbit ($e = 1$), keeping the sum of the radii $r_1 + r_2$, the length of the chord c and the semimajor axis a all fixed in value, and the time-of-flight will be unchanged. The transformation is illustrated in the following figure:

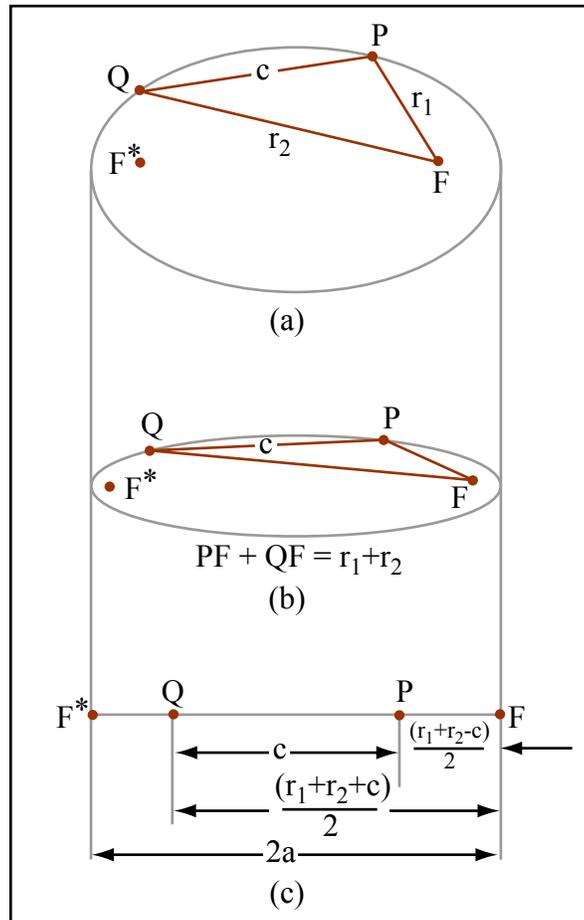

Figure by MIT OpenCourseWare.

The flight time for the rectilinear orbit is

$$\begin{aligned} \sqrt{\frac{\mu}{a^3}}(t_2 - t_1) &= (\alpha - \sin \alpha) - (\beta - \sin \beta) \\ &= (E_2 - \sin E_2) - (E_1 - \sin E_1) \end{aligned}$$

in terms of the Lagrange parameters and the eccentric anomalies.

Transformation of the Four Basic Ellipses

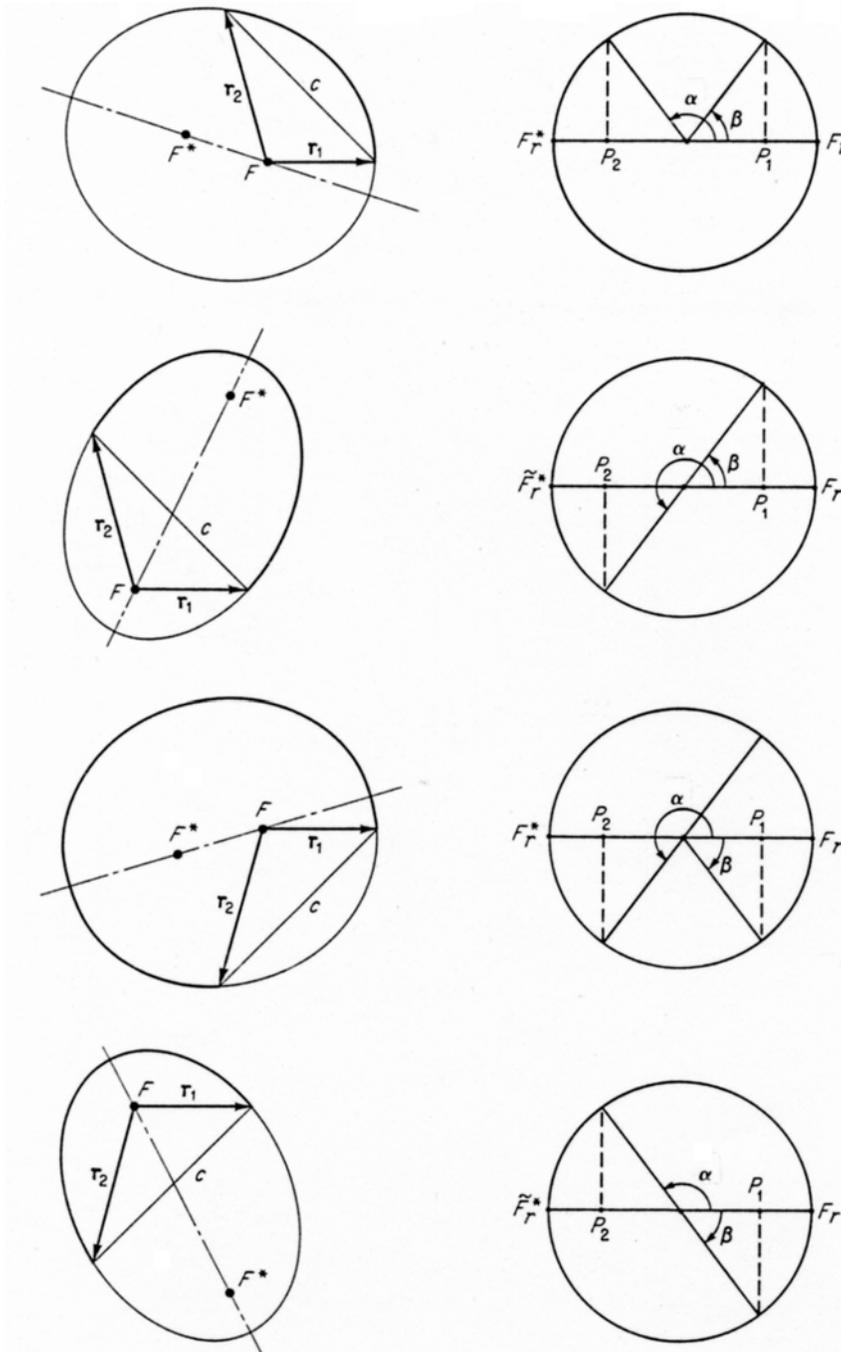

Fig. 6.20 from *An Introduction to the Mathematics and Methods of Astrodynamics*. Courtesy of AIAA. Used with permission.

We adopt the convention for assigning quadrants to the Lagrange parameters α and β

$$\begin{array}{lll} 0 \leq \alpha \leq 2\pi & 0 \leq \beta \leq \pi & \text{for } \theta \leq \pi \\ 0 \leq \alpha \leq 2\pi & -\pi \leq \beta \leq 0 & \text{for } \theta \geq \pi \end{array}$$

which will include all elliptic orbits.
