

How do genetic algorithms relate to their biological origins?

How do they relate to human processes of design?

Why is there power in this metaphor?

How can they be used to extend the capabilities of the designer?

MIT Design Inquiry

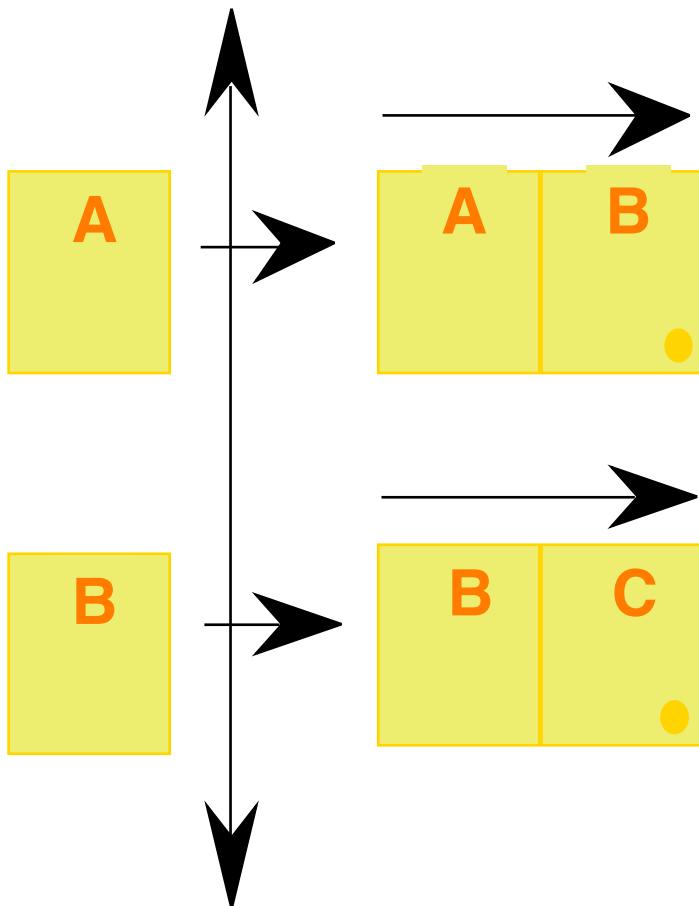

How do genetic algorithms relate to their biological origins?

- Separation of genetic material (genotype [representation]) from organism (phenotype [design])
- Expressing genotype as organism
- Organism carries genotype and reproduces genotype using ‘genetic’ processes of crossover and mutation
- Darwin’s natural selection uses fitnesses of organisms in their environment to improve the gene pool
- GA is a simple model of this process

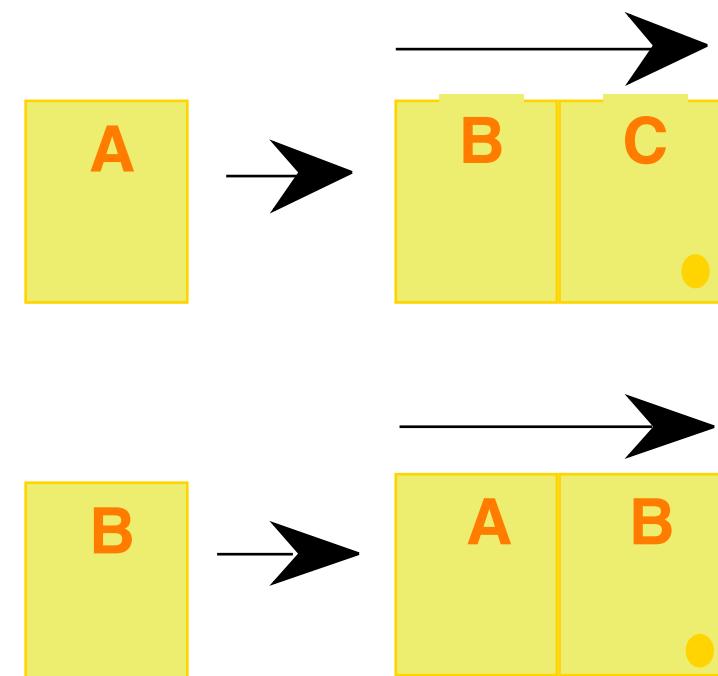

Genetic processes

Parents

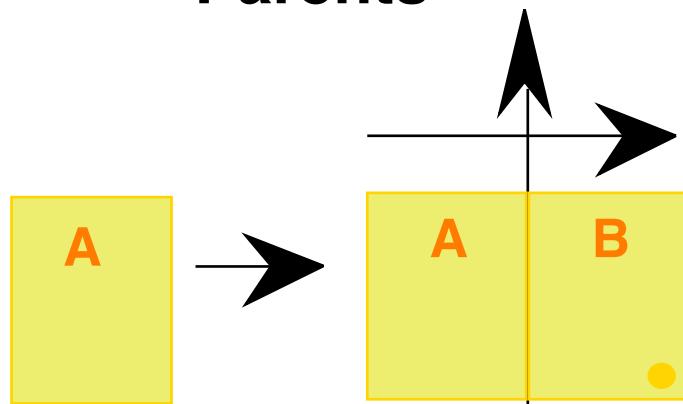

Offspring

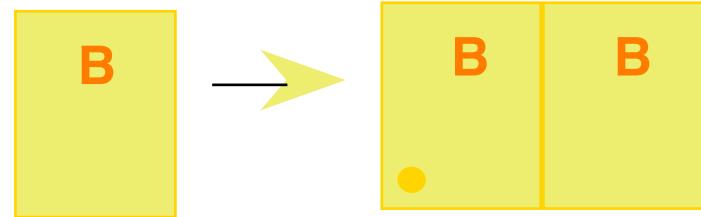

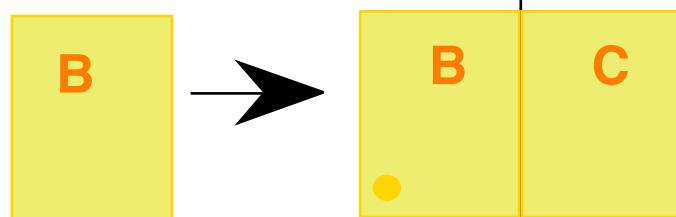

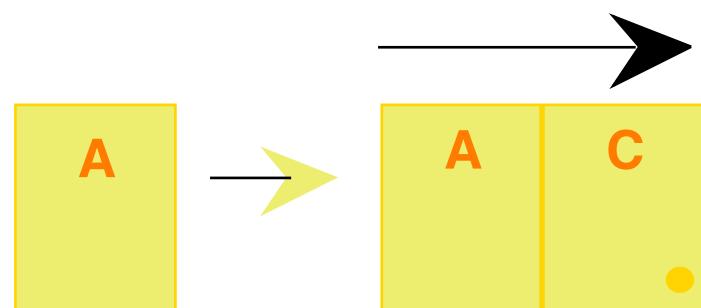

Crossover point

Parents

Offspring

Crossover point

How do they relate to human processes of design?

- Can map genetic representation onto a computational representation of a design; can map phenotype onto a interpretable view of a design
- Humans work on single or few designs at a time/ genetics works on a population of ‘designs’ in parallel
- Humans can be seen to “search” design spaces - this is one interpretation of what GAs are doing.

Why is there power in this metaphor?

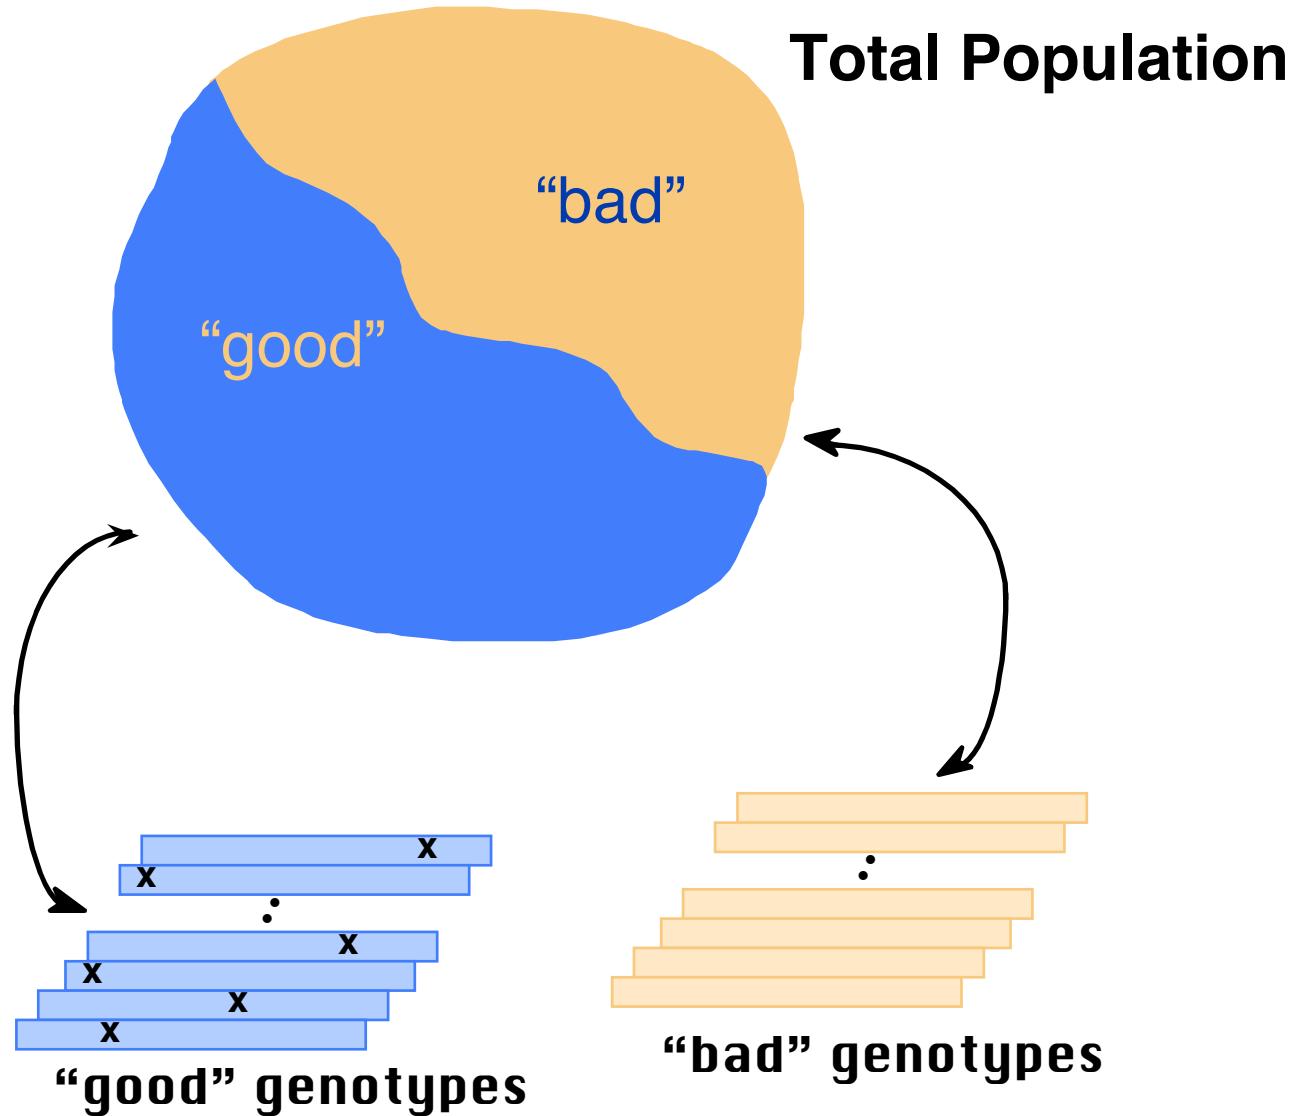

- Guaranteed improvement - Darwinian evolution
- Large scale search
- Blind search
- Fitness can be human evaluation
- Fitness can change over evolutionary time
- Can produce complexity
- Can produce unexpected results

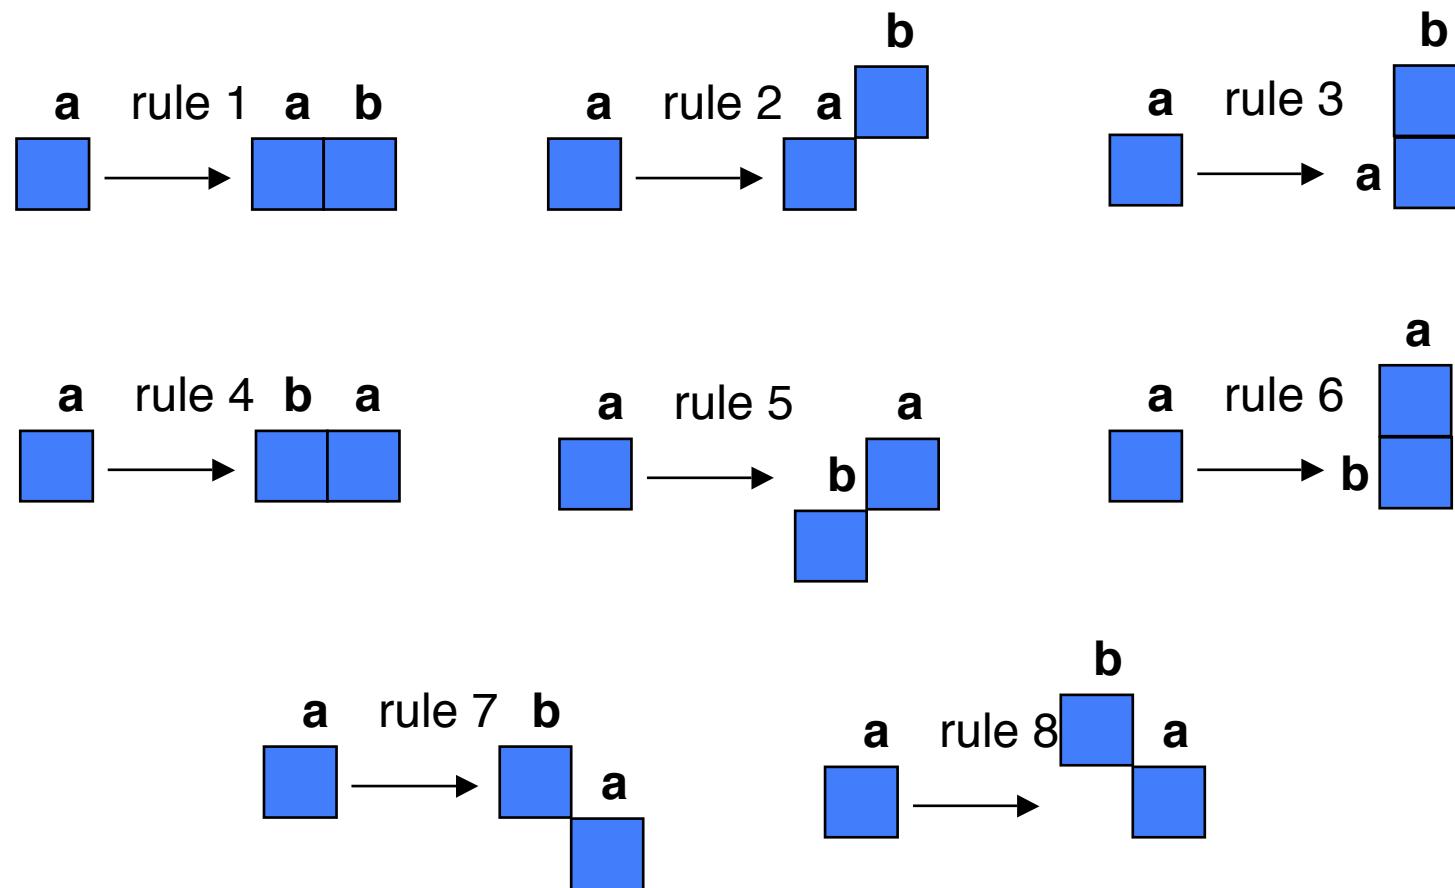

How can they be used to extend the capabilities of the designer?

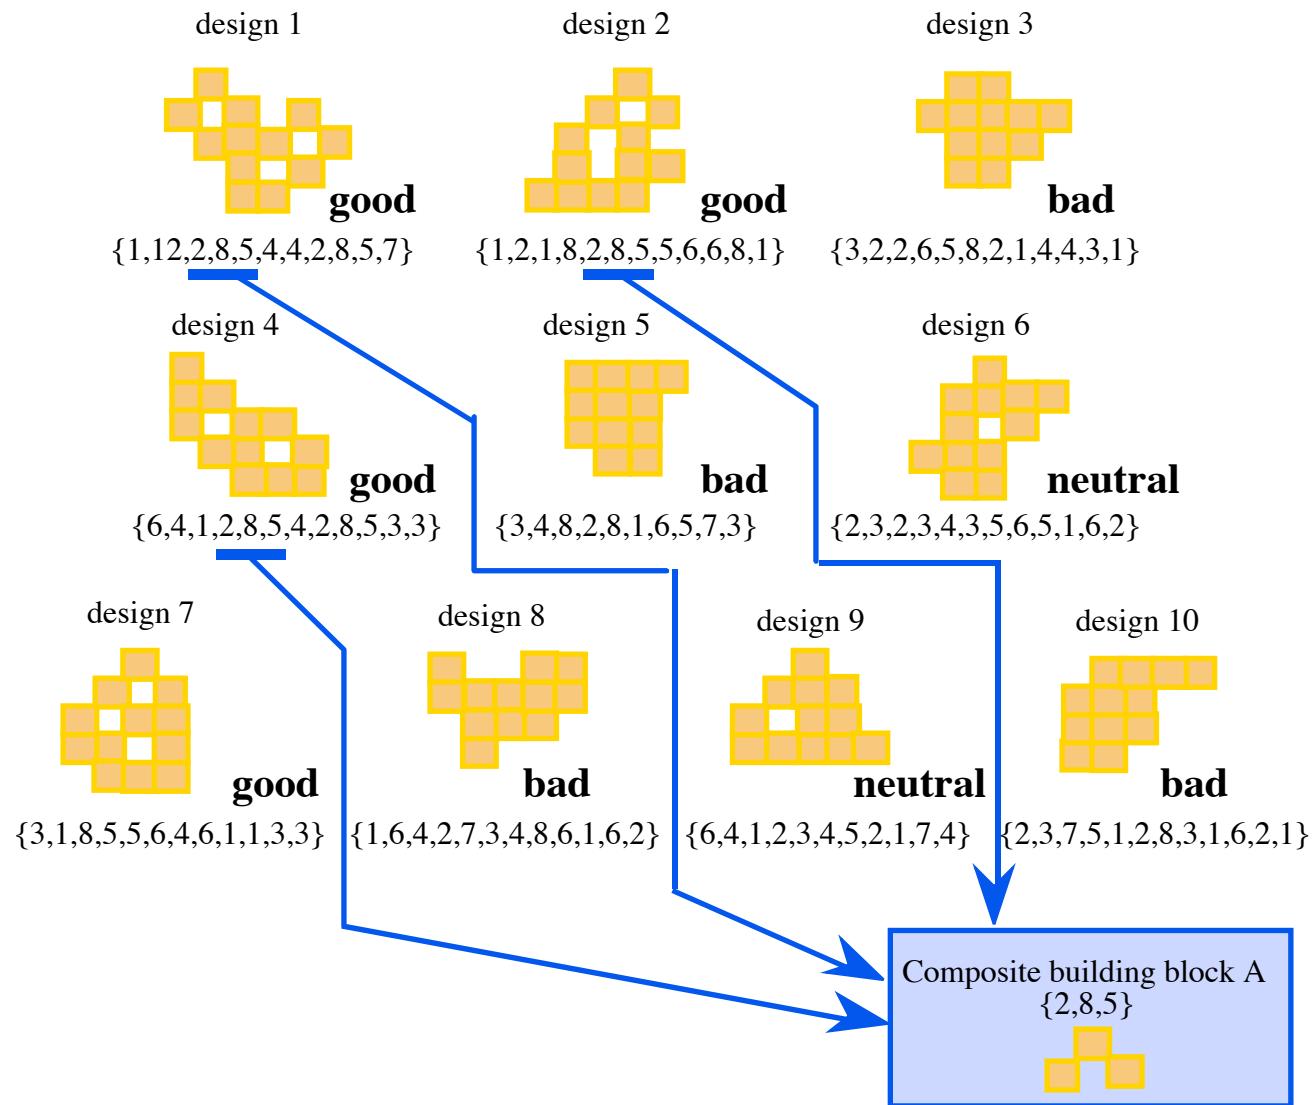

- Creativity through genetic engineering
- Novel designs through extending genetic crossover
- Novel designs through different fitnesses

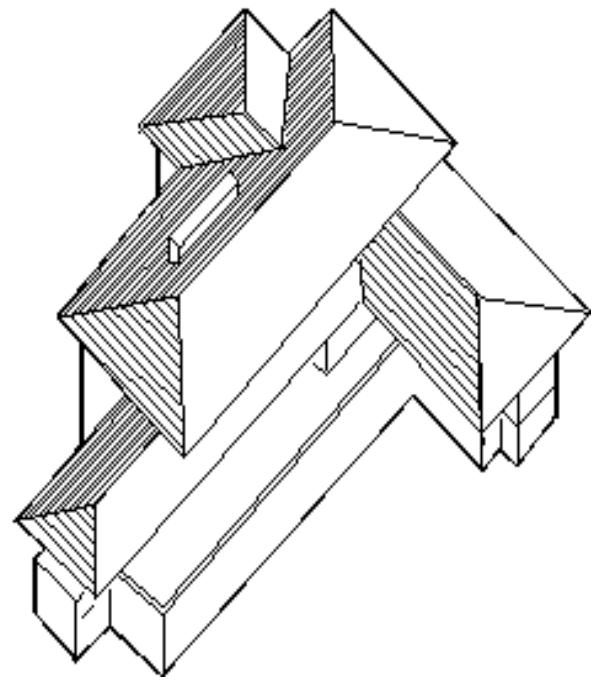

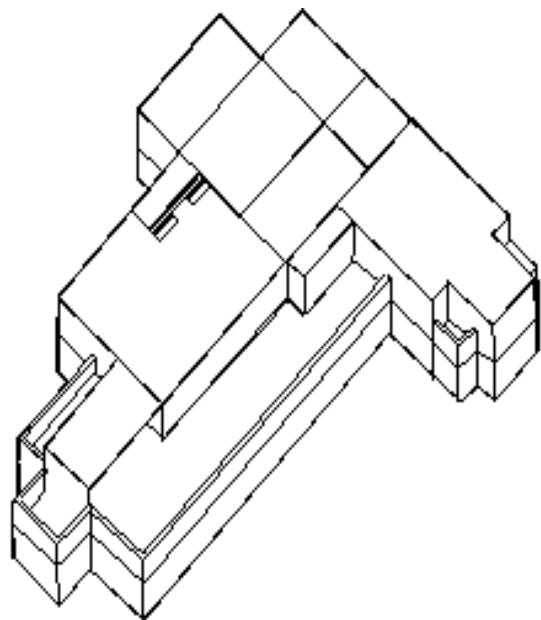

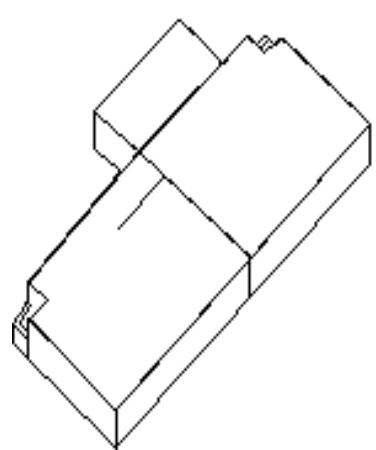

Genetic Engineering and Creative Design

- Background
 - genes, genotype, phenotype, fitness
- Connecting genes to performance in fitness
- Emergent gene clusters ⇒ evolved genes

Mondrian

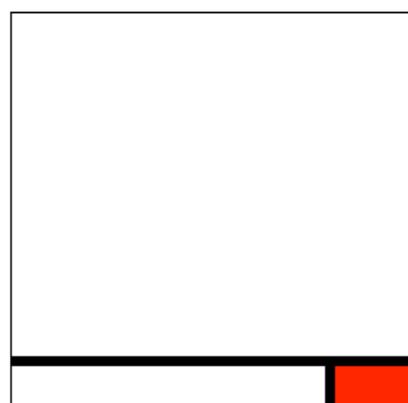

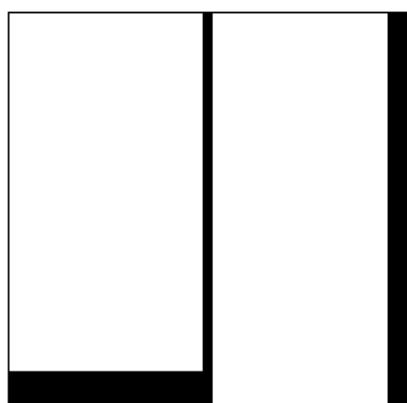

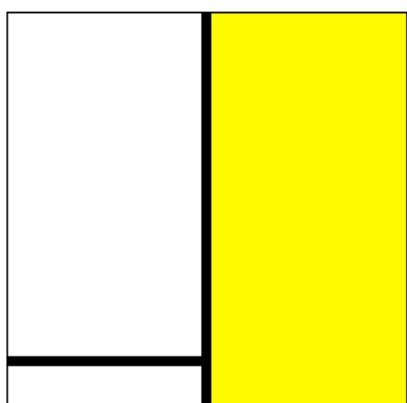

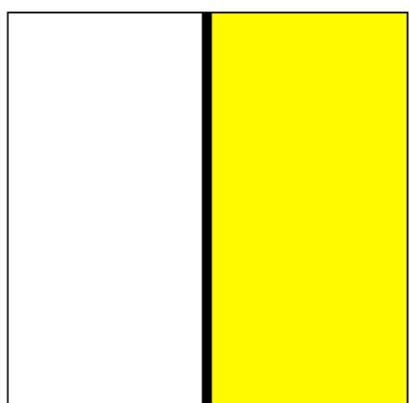

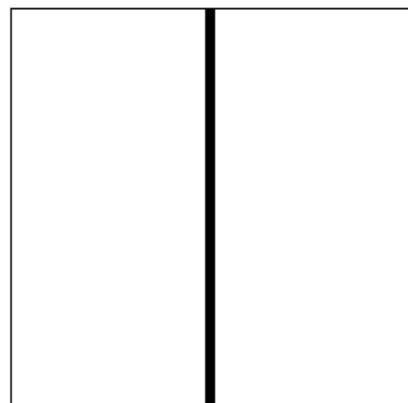

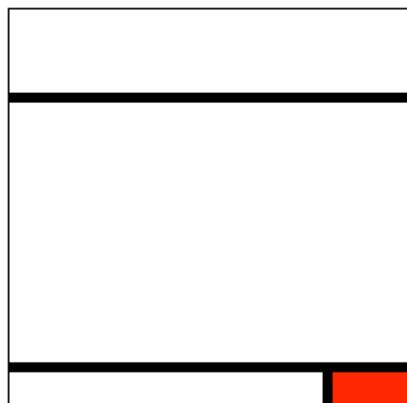

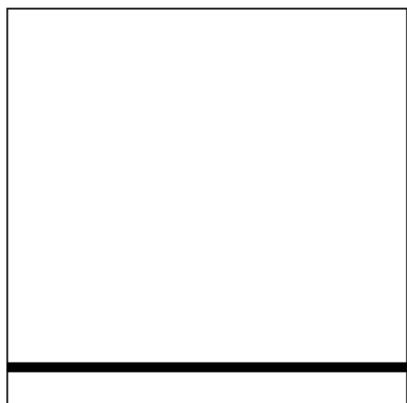

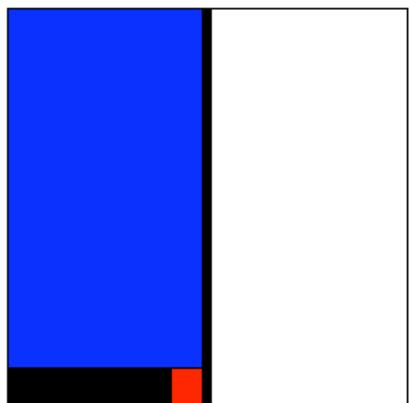

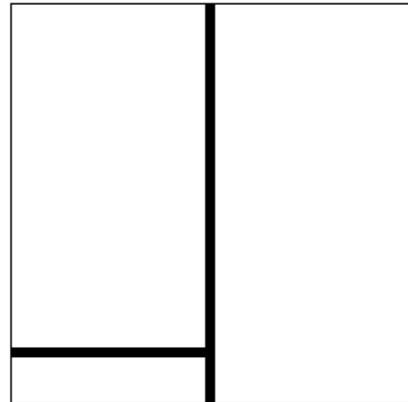

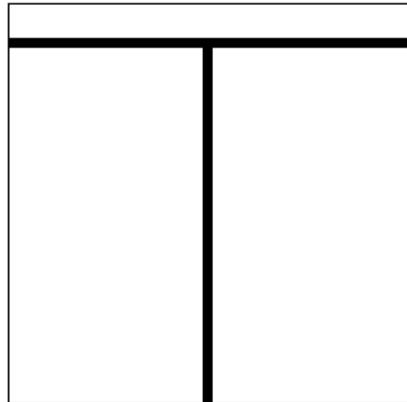

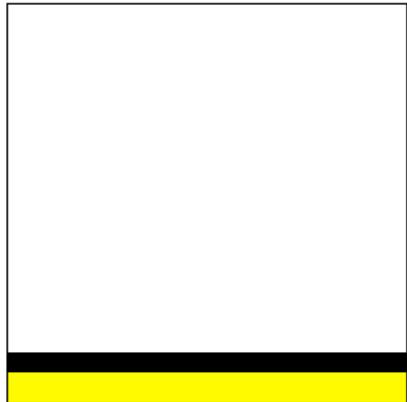

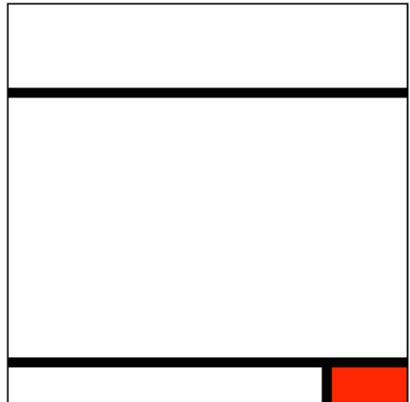

Genotype Form

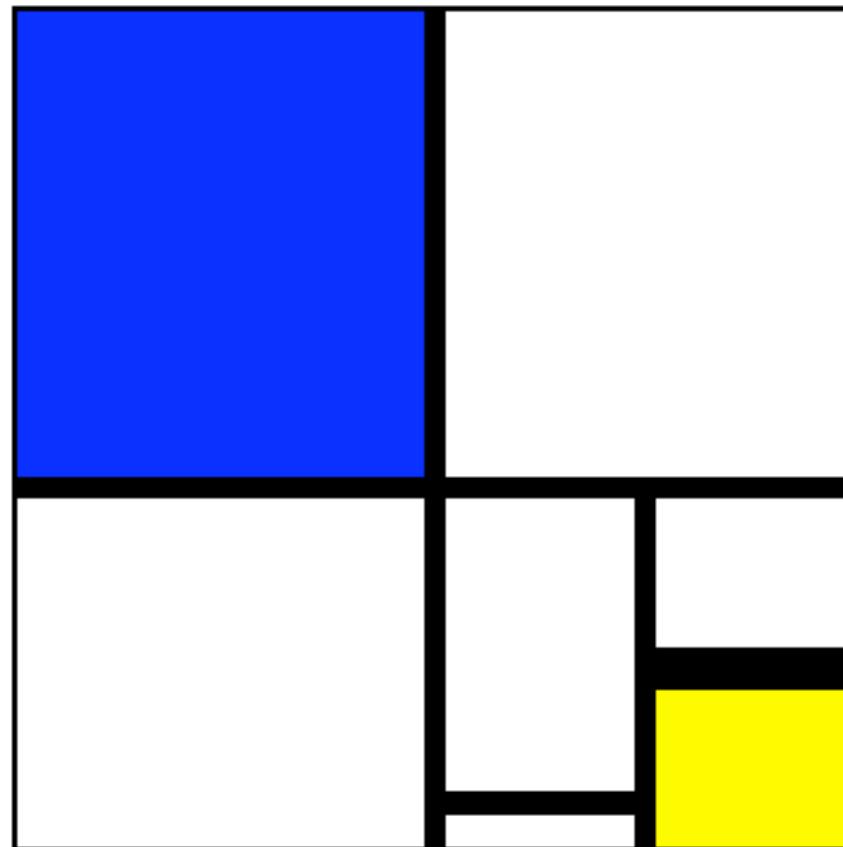

- In form of a tree
- Each node has four variables
 - direction of rectangular split (4 values)
 - fraction of the split (15 values)
 - colour of split area (10 values)
 - line width (3 values)

Fitnesses for Representation

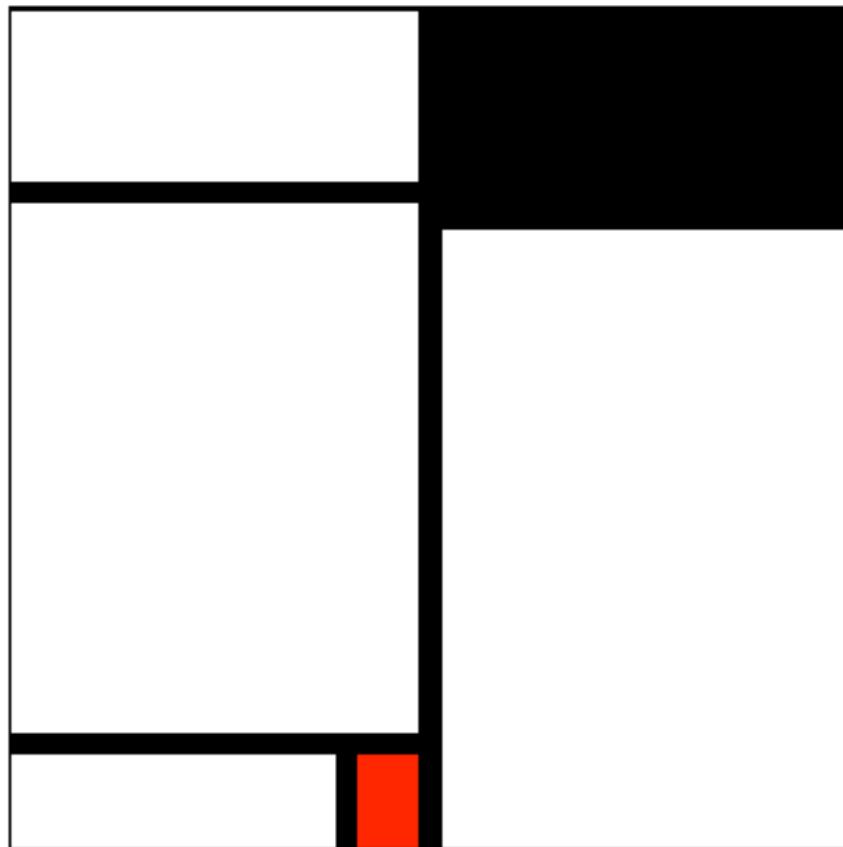

- offset between actual and required positions of dissection lines
- number of lines with correct line width, normalised
- number of correct colour panels, normalised
- number of lines assigned, normalised
- number of unassigned lines, normalised

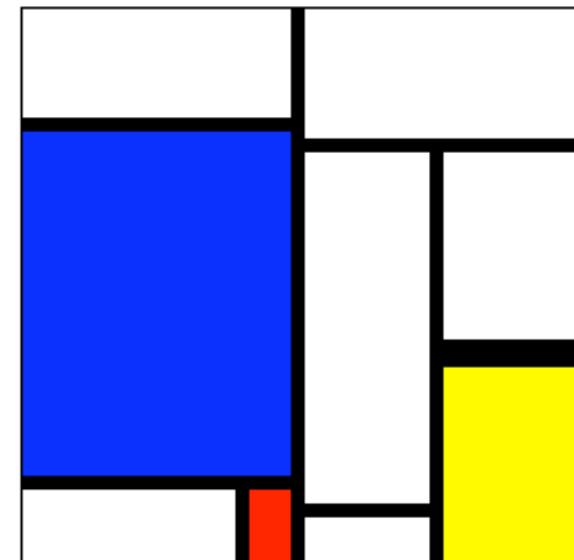

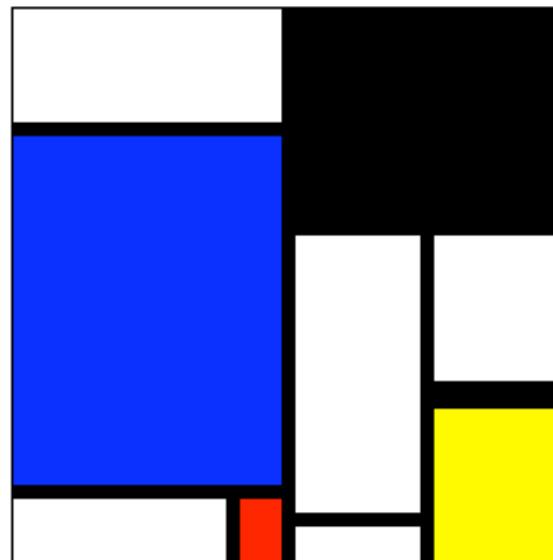

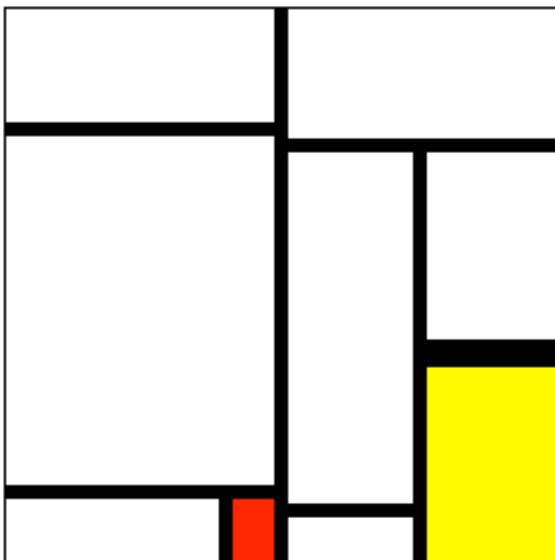

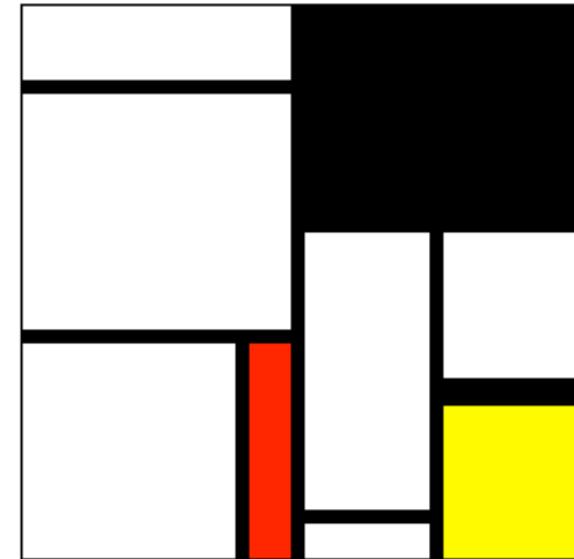

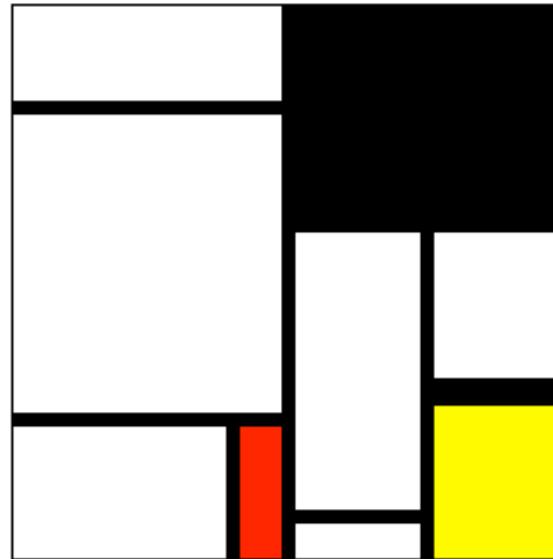

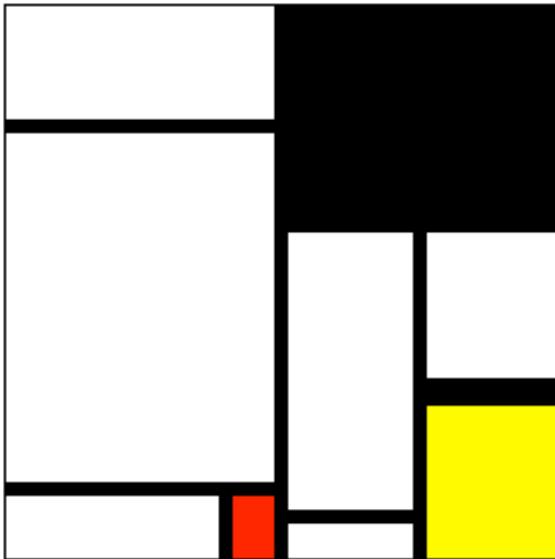

Genetically Engineered Mondrian

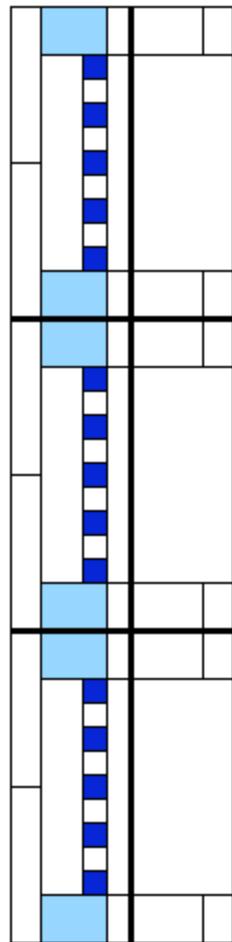

Genetically Engineered Mondrian

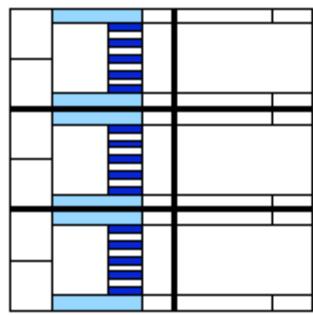

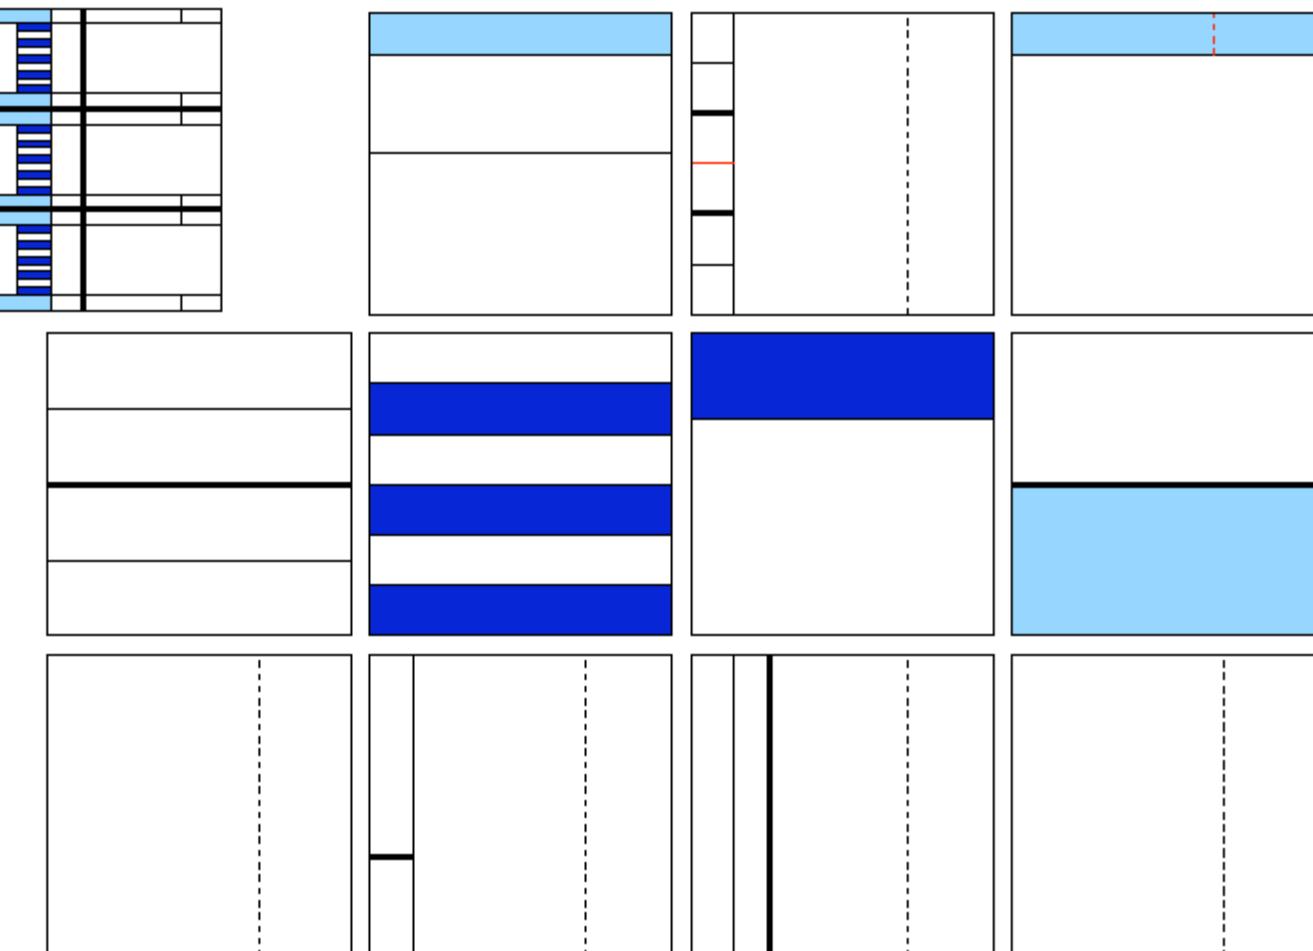

Genetically Engineered Frank Lloyd Wright Windows

(a)

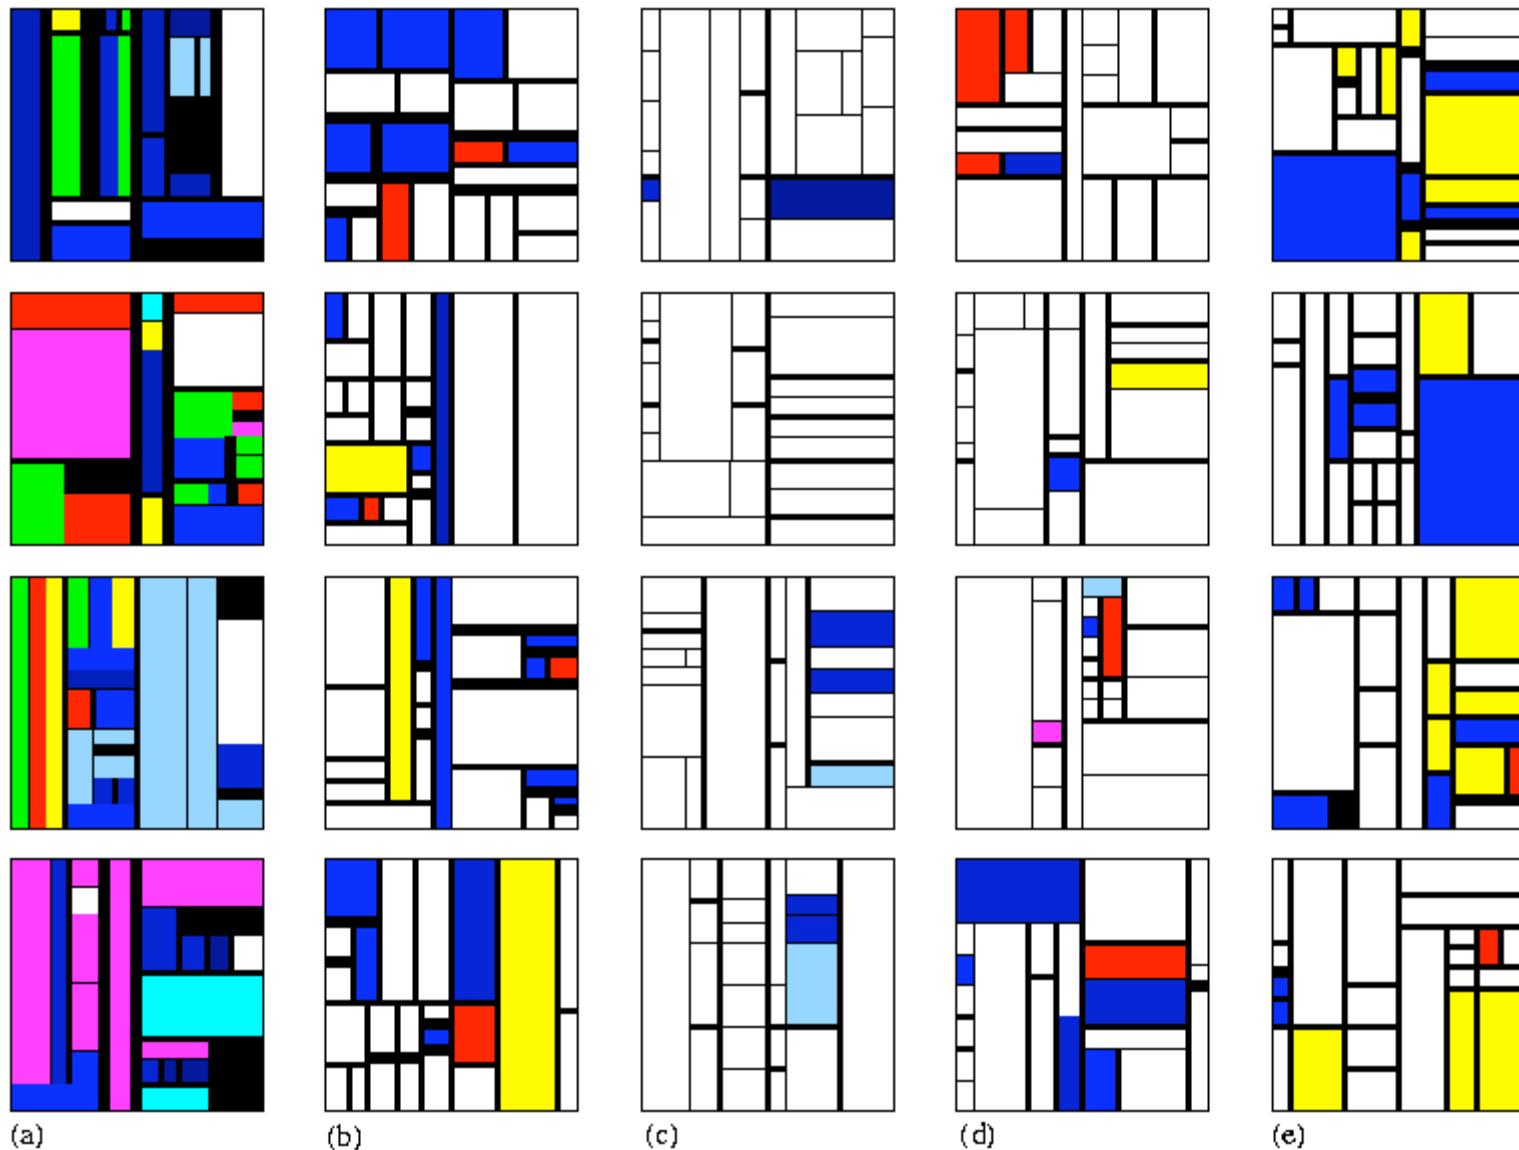

(b)

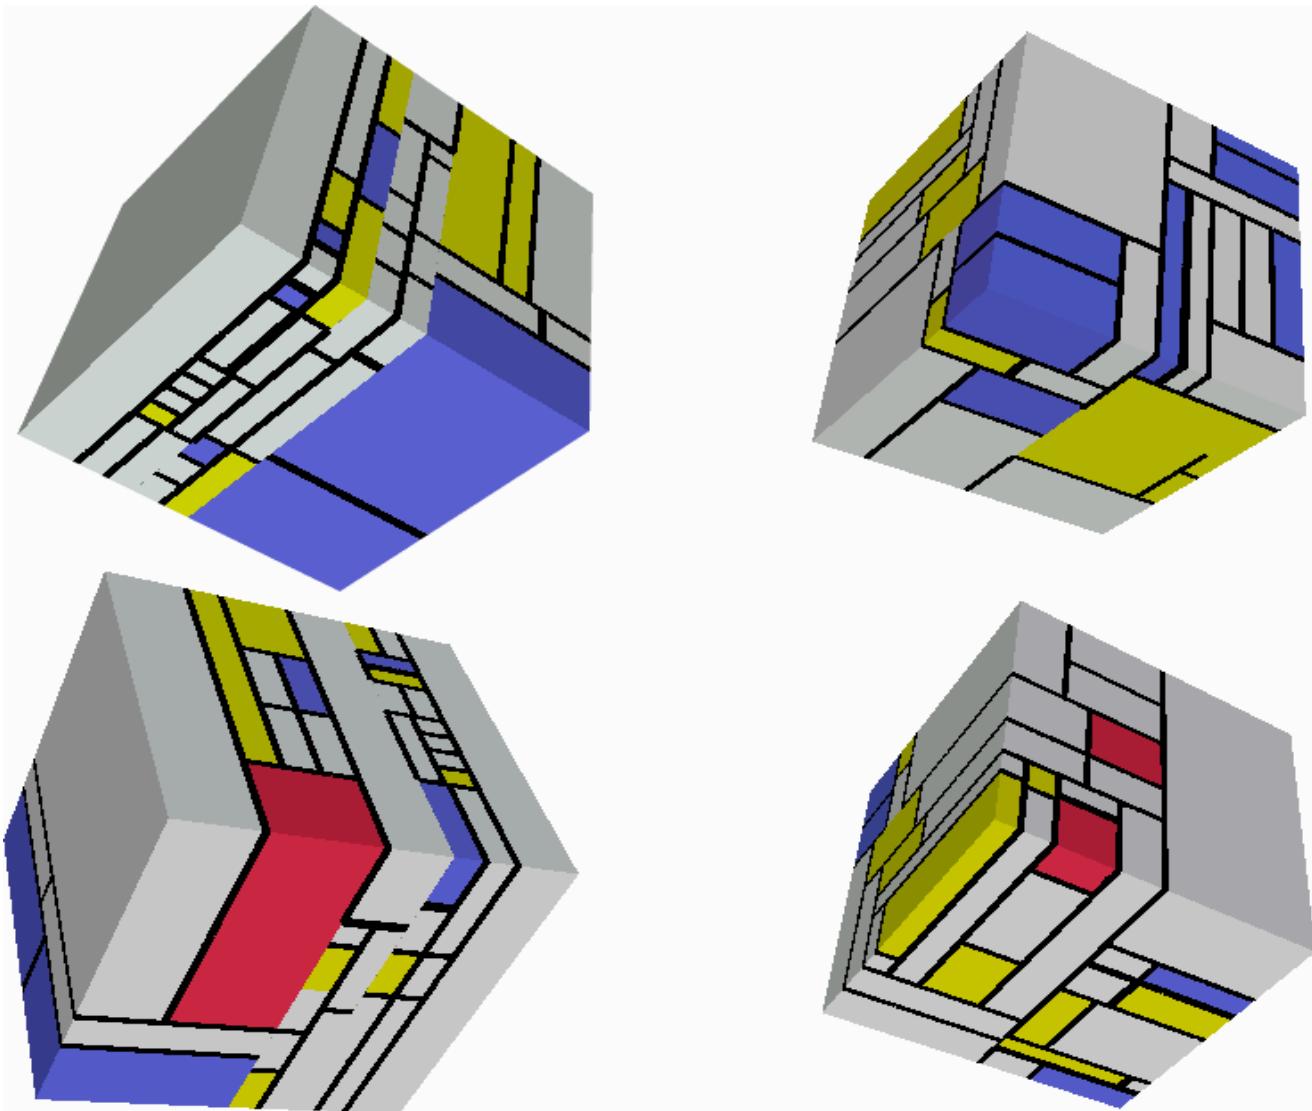

(c)

Flondrians

- Mondrian painting ⇒ genetically engineered genes: M-genes
- Frank Lloyd Wright windows ⇒ genetically engineered genes in same representation: F-genes
- “Flondrians” are the genetic product of mating M-genes with F-genes
