### CO<sub>2</sub> CONTENT FOR BUILDING MATERIALS

Based on the research conducted by MIT students, we conclude that one unit of building material (by mass) installed in a Boston building is responsible for the following portion of its mass in CO<sub>2</sub> emissions:

| <u>Material</u>                        | <u>CO<sub>2</sub> emissions as % of mass</u> |
|--|--|
| Autoclaved Aerated Concrete            | 0.79   |
| Concrete                               | 0.20   |
| w/ 30% fly ash replacement             | 0.18   |
| Rebar                                  | 0.76   |
| Hot-rolled steel sections <sup>1</sup> | 0.80   |
| Cold-formed steel <sup>2</sup>         | 1.70   |
| Glu-lam timber                         | 0.80   |
| Dimensional lumber                     | 0.05   |
| Plywood                                | 0.50   |
| Brick                                  | 0.23   |
| Concrete masonry units (CMU)           | 0.19   |
| Glass <sup>3</sup>                     | 0.18   |
| Rammed earth <sup>4</sup>              | 0.01   |

In other words, one ton (2000 lbs) of plywood gives off 1000 lbs of CO<sub>2</sub> and 1000 kg of hot-rolled steel gives off 800 kg of CO<sub>2</sub>.

<sup>1</sup> This includes all standard sections such as I-beams, pipes, angles, tubes, etc.

<sup>2</sup> This is for light-gauge steel such as lightweight galvanized steel framing and lightweight corrugated steel decking for concrete slab construction.

<sup>3</sup> This is for float glass, such as ordinary 1/8" or 1/4" glass, and does not include insulated units or structural glass.

<sup>4</sup> This number would be significantly higher if the soil were stabilized with cement. For significant amounts of cement, the CO<sub>2</sub> content would lie between the value for concrete and rammed earth, and would be closer to 0.10.
