Ch. 9 Brock

General properties of viruses

- Replicate independently of the chromosome of cells, but dependent on cells
- Infect animals (and people), plants, and bacteria (**bacteriophage**)
- Extracellular forms (**virions**) are metabolically inert
- Contain either DNA or RNA
- Range in size from about 28 nm to about 200 nm in diameter
- Important tools for microbial geneticists and genetic engineers

- Subunits comprising the capsid are **capsomeres**
- Viral capsids are capable of **self-assembly**
- Rod-shaped viruses have **helical symmetry** and spherical viruses have **icosahedral symmetry**

Additional viral structures

- Some animal viruses are **enveloped**
 - Membrane is derived from host cell
 - Protein is viral-encoded
- Some bacteriophage are **complex**
 - Icosahedral heads
 - Helical tails
 - Complex tail structure

Viral growth

- Number of infectious units in a viral suspension is called the **titer**
- Can enumerate **plaque-forming units (PFU)** on lawns of host cells
- **Plating efficiency** is the ratio of PFU/total virions

Animal virus methods

- Animal cells can be primary or continuous culture cell lines
- Plaque assays as well as cytopathic effect (CPE) can be observed

Viral replication

- During **eclipse** there are no intact virions
- **Maturation** begins with packaging of nucleic acid
- **Latent period** begins at entry and ends with release
- Lysis results in **one-step growth**
- **Burst size** = yield

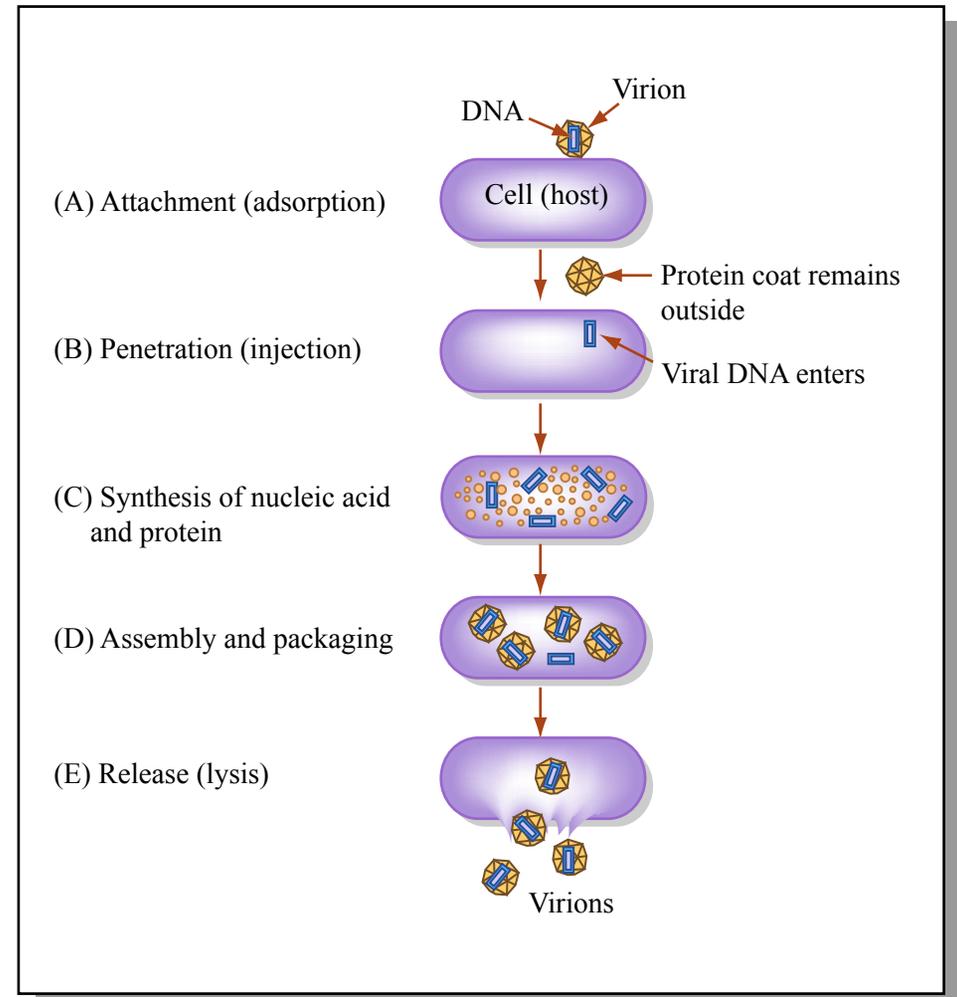

Figure by MIT OCW.

Attachment and penetration

- Virion binds specific receptors on the host cell surface
- Penetration leads to viral uncoating
- Restriction endonucleases can cleave bacteriophage DNA

Virulent bacteriophage

- T-even phage are closely related
 - T4 is best studied
- ds linear DNA
 - 169 kb (> 250 proteins)
 - Circularly permuted
- 5-hydroxy-methylcytosine
 - Glucosylated base is resistant to restriction enzymes

Temperate bacteriophage

- Can complete lytic cycle or become a prophage (lysogeny)
 - Most viral genes not expressed
 - Genome replicated synchronously with host genome
- Lysogens can become activated and undergo lytic replication

Phage lambda

1. DNA circularizes
2. Expression of N and Cro
3. Antitermination L1 and L2 (some Q)
4. Q antitermination R2
5. Cro acts as a repressor on O_L and O_R
6. Blocks expression of cI and cII (lysis)
7. Rolling circle replication

Lysogeny

- To prevent late gene expression, cI (lambda repressor) must be expressed
- P_E is activated by cII
- Stabilized by cIII
- cI also represses at O_L and O_R , but in opposite order of Cro (lysogeny)
- P_M is activated once O_R is fully bound by cI
