Objective: Learn how cell signaling network operation – in multi-pathway manner -- differs between normal and disease state or among various individuals

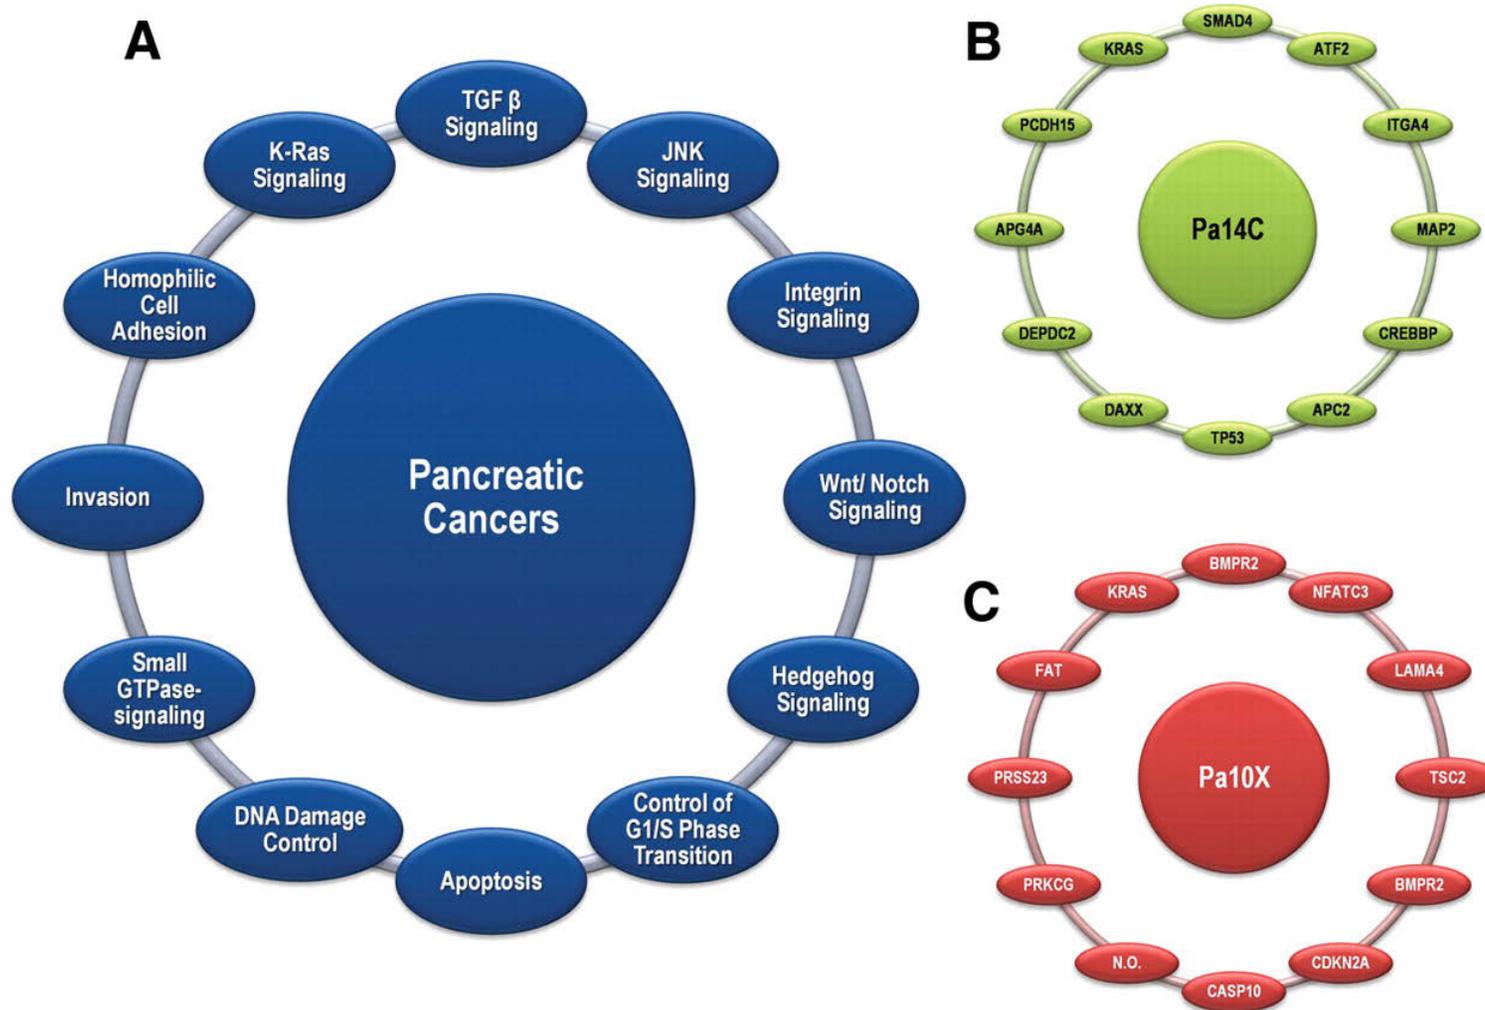

Example: Myriad -- and highly diverse -- genetic alterations (amplifications, deletions, mutations) across pancreatic tumors... (as well as in breast, colon, brain)

Pathway / Interactome Databases hold substantial ‘prior knowledge’ for integrative analysis of multi-pathway network effects; but, there is need to move forward from illustration to prediction

Shortcomings:

Node Source

- ≥ 2
- GeneGo
- KEGG
- NCI-PID
- NetPATH
- PANTHER
- Reactome

- Typically diverse with respect to specificity and context – i.e., cell type, genomic content, and/or environmental conditions
- Do not readily permit ‘input-output’ calculation of network operating behavior, and thus difficult to relate to phenotype and/or interventions

© source unknown. All rights reserved. This content is excluded from our Creative Commons license. For more information, see <http://ocw.mit.edu/help/faq-fair-use/>.

Central Goal:

Establish methodology for converting from qualitative cell pathway topology 'maps' to quantitatively computable network models

Approach:

Employ logic-based modeling framework, to train qualitative 'prior knowledge' maps to quantitative empirical data for system context and multi-pathway comparisons of interest

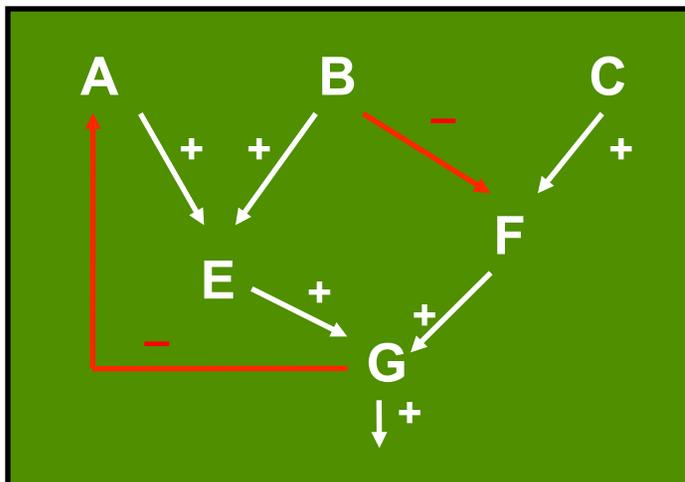

More Detailed Insights from Stronger Modeling Analysis
-- integrating empirical data with prior knowledge
using network logic approach

Generic Pathway Map

(e.g., Ingenuity)

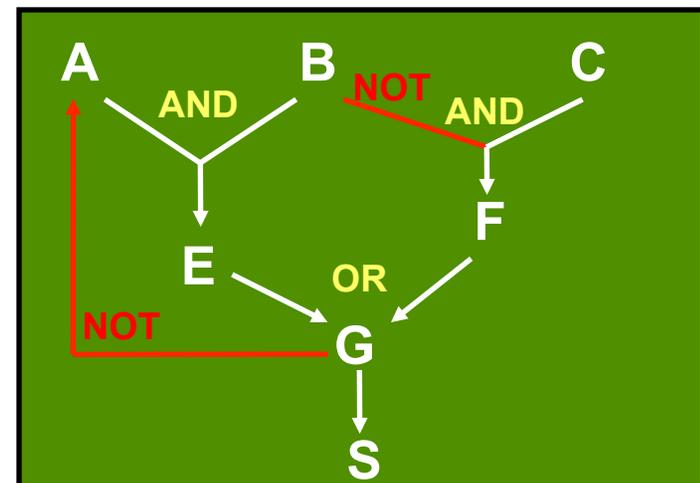

**nodes (=compounds),
signed directed edges
(activation +, inhibition -)**

Network Logic Model

Boolean operators:

AND / OR / NOT

Example Study: Comparative Hepatocellular Cell Signaling Network Operation in Inflammation Context

hepatocellular lines

Primary Hepatocytes

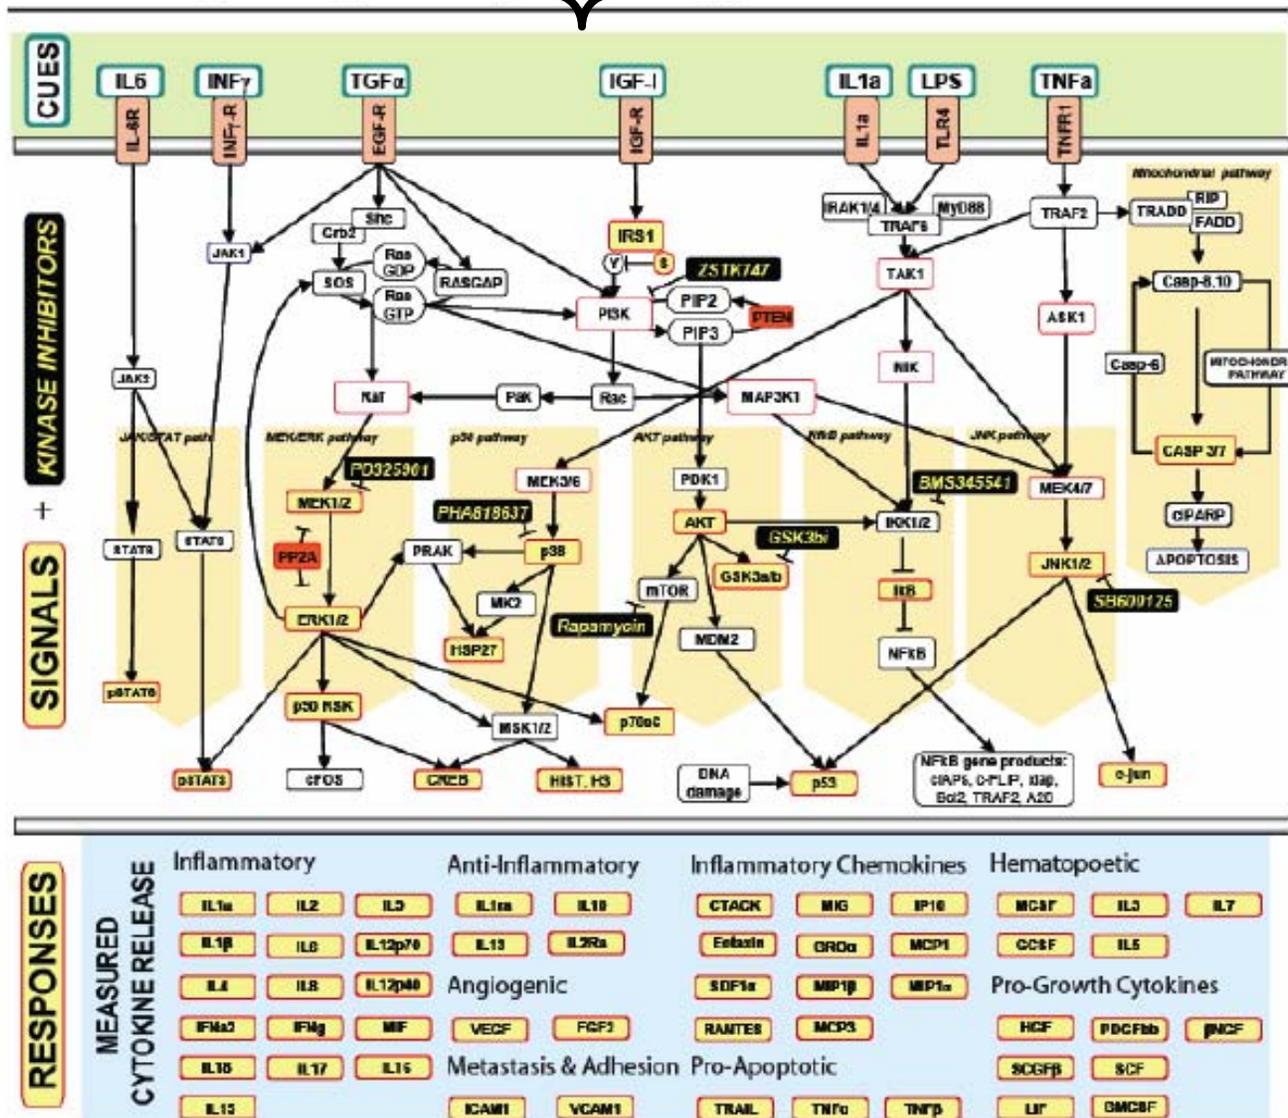

HepG2

Huh7

Hep3B

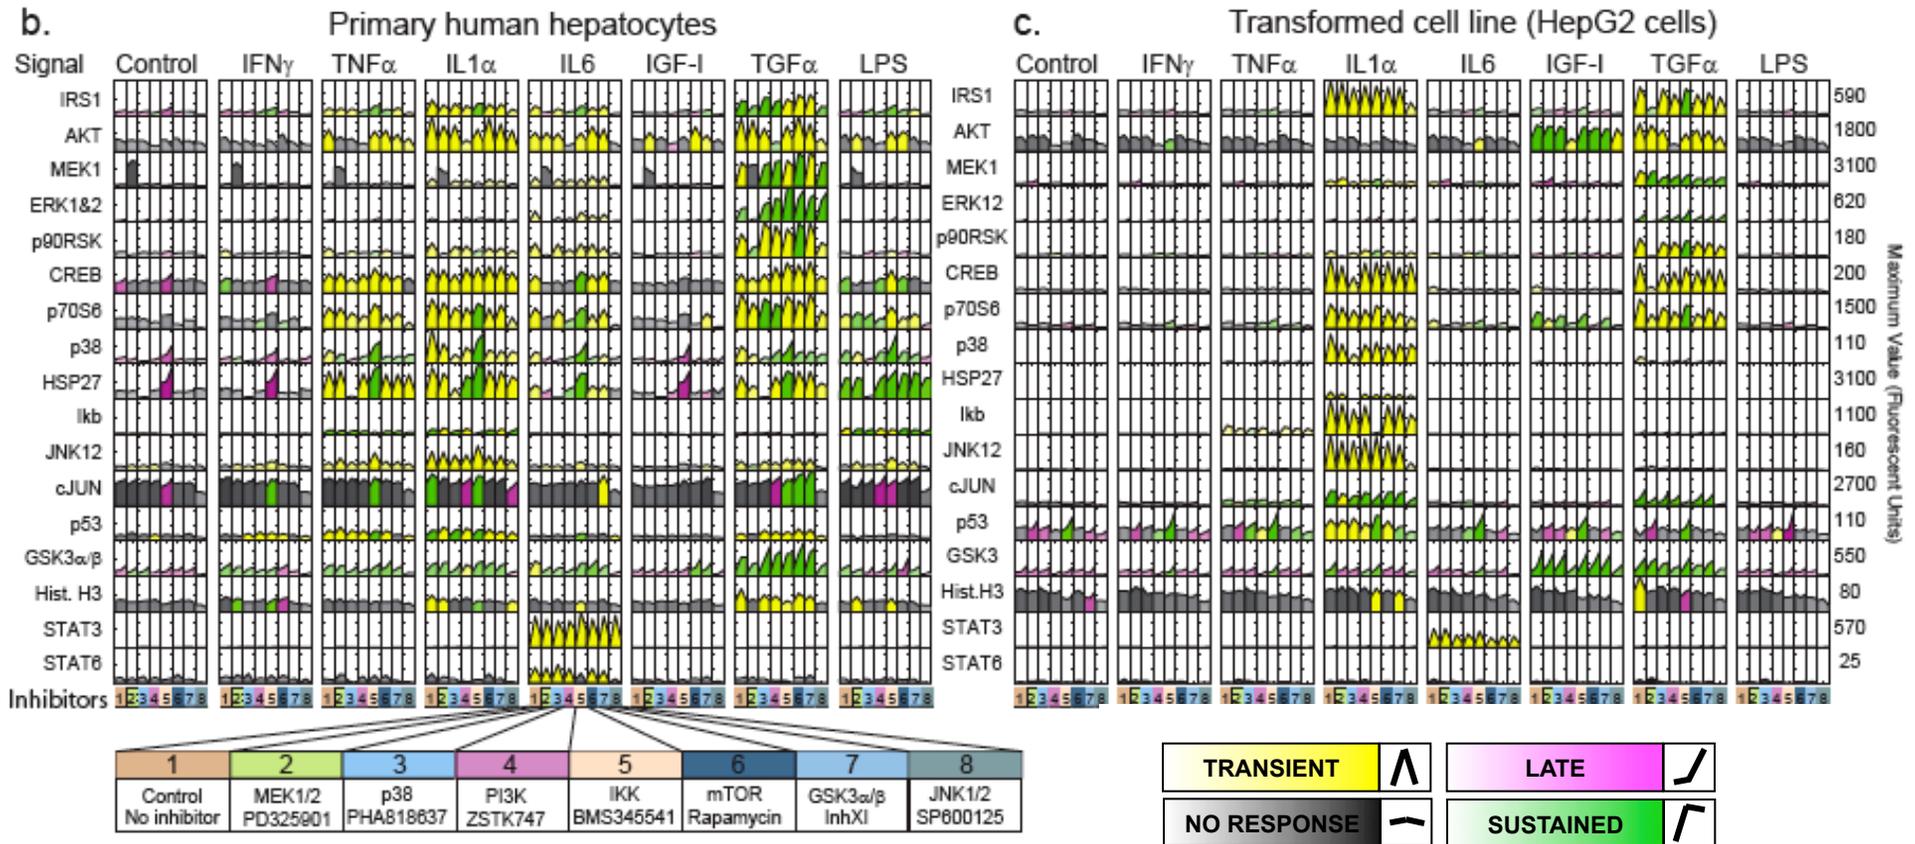

Focus

[7 ligands + control]
 X [7 inhibitors + control]
 X 17 signals
 = ~ 1000 measurements for each cell-type and time-point and replicate

Multi-Pathway Phosphoproteomic Data – primary human hepatocytes, HepG2 hepatocellular line

Time-points: 0, 30 min, 3 hrs

© source unknown. All rights reserved. This content is excluded from our Creative Commons license. For more information, see <http://ocw.mit.edu/help/faq-fair-use/>.

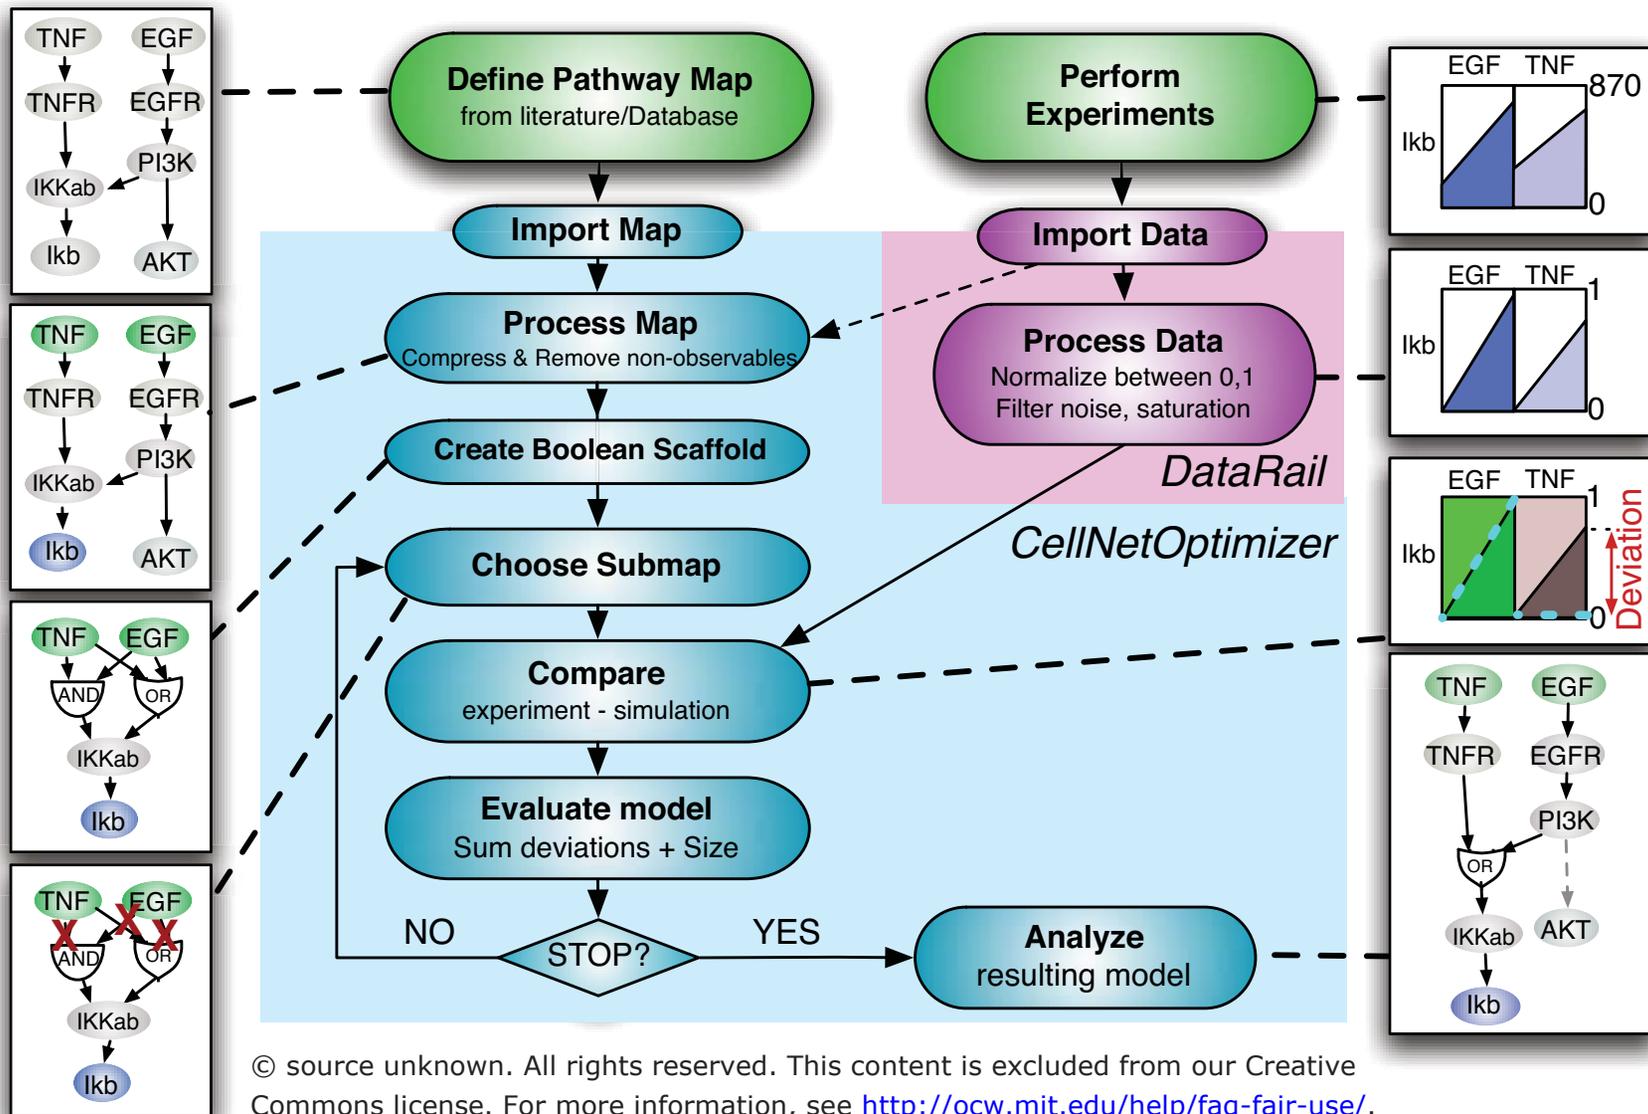

-- also cell death, proliferation index, and production of ~50 cytokines
for each condition

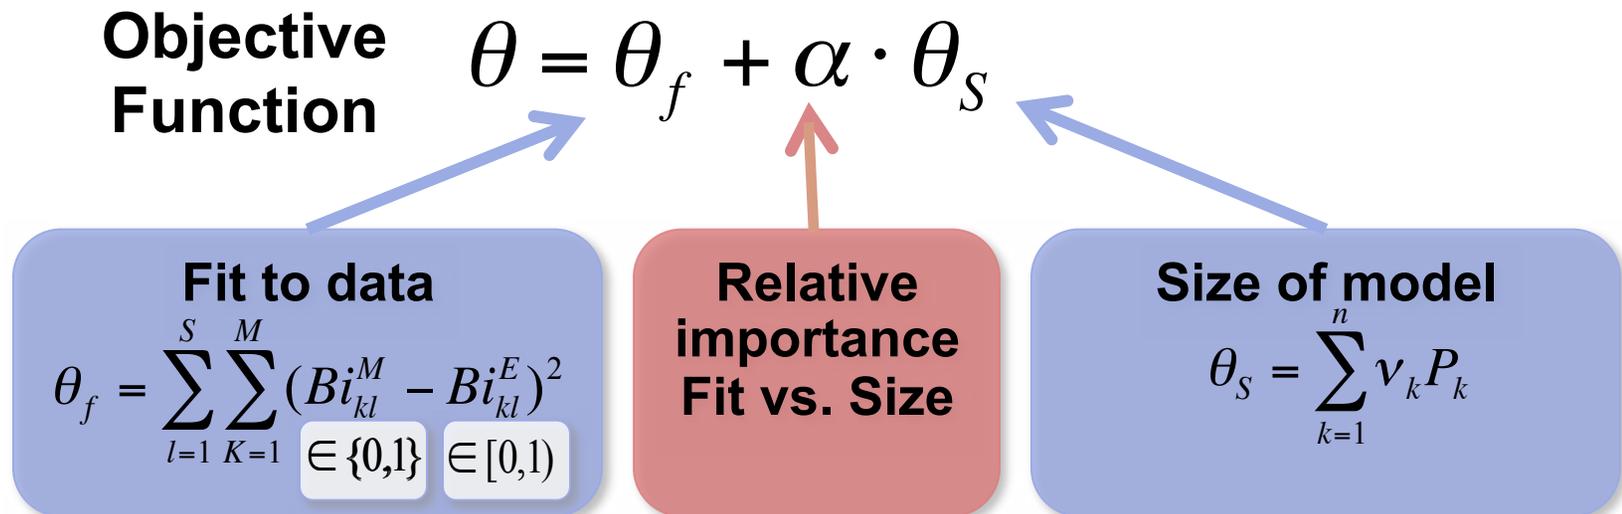

**Example Database
Pathway Map
from literature curation,
for network responses
to our cytokine and
growth factor treatments**

from *Ingenuity*
supplemented by
some literature
knowledge for key
receptors
-- 82 nodes,
116 edges

Training Prior Pathway Map Knowledge on Context-Specific Empirical Signaling Data

Automated Development of Logic Network Models from Fit of Generic Pathway Map to Experimental Data as an Optimization Problem

© source unknown. All rights reserved. This content is excluded from our Creative Commons license. For more information, see <http://ocw.mit.edu/help/faq-fair-use/>.

- minimize Objective Function (θ) across model variants (P),
 - trading off model-data error and model size;
- α ascertained by Pareto optimum for false-positive vs false-negative trade-offs
- obtain family of best-fit models (within 1% of Objective Function optimum)

Automated Development of Logic Network Models from Fit of Generic Pathway Map to Experimental Data as an Optimization Problem

Genetic Algorithm

- 1. Initialize a population of model variants (from Ingenuity scaffold or from random scaffolds)**
- 2. Evaluate objective function (model-vs-data error plus model-size penalty) for each individual in the population**
- 3. Generate next generation of population using Elite Survival, Fitness Selection, Mutation, and Crossover**
- 4. Assess whether stop criterion is fulfilled, or iterate back to step 2**
- 5. Model pruning to reduce model size without detriment to model-vs-data error**
- 6. 100 runs for each value of model-size penalty α**

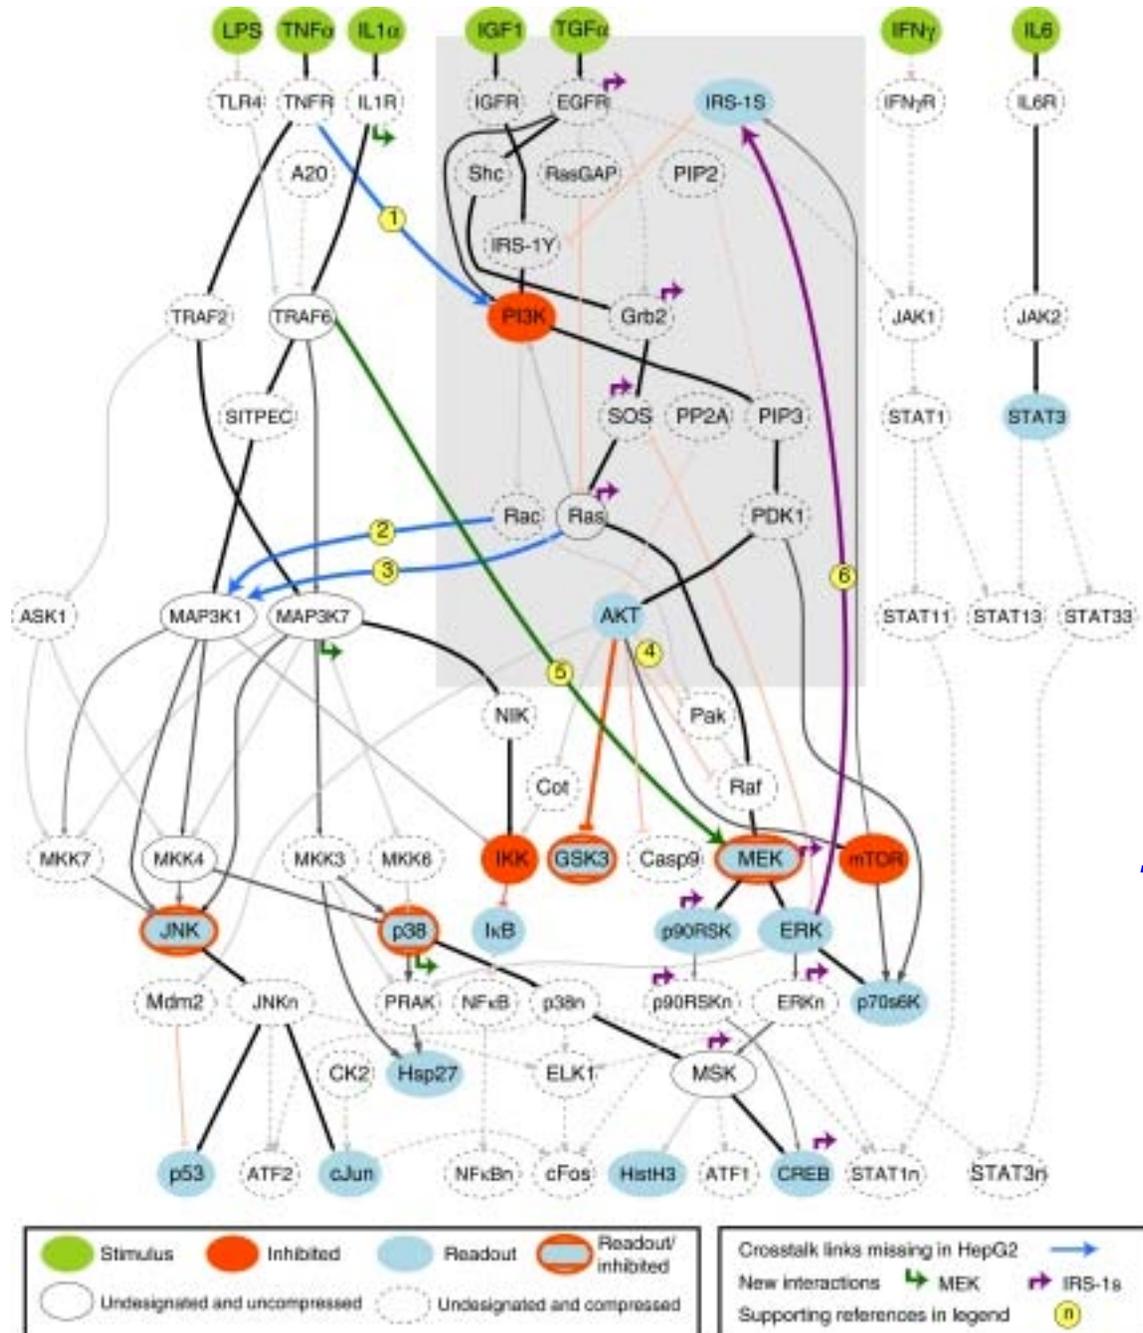

Illustration for HepG2 cell line

– improvement in data fit from best-fit original scaffold model to best-fit trained model

Training data fit to ~9% error, substantially improved from original scaffold model fit of >45% error

Illustration for HepG2 cell line

- consensus model from fit of empirical data to initial prior knowledge scaffold
- additional arcs needed to improve model fit, support in literature though not in prior knowledge scaffold
- arcs present in other cell line models but not in HepG2

Molecular Systems Biology 5, no. 1 (2009).

Model size is fairly insensitive to size penalty

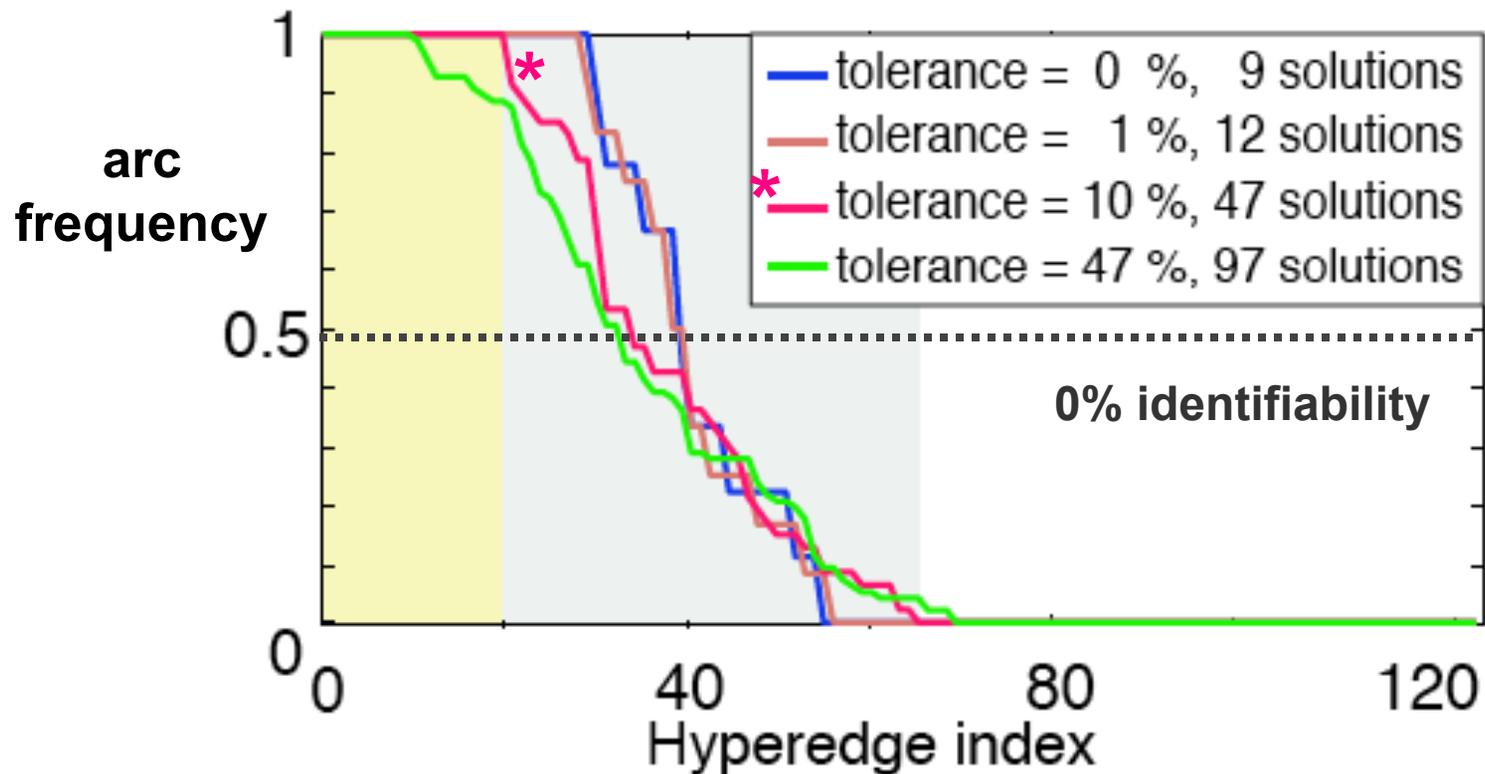

Objective function = Fit of data (MSE) + α Size

© source unknown. All rights reserved. This content is excluded from our Creative Commons license. For more information, see <http://ocw.mit.edu/help/faq-fair-use/>.

Models can only be partially identified -- thus model families are best outcome

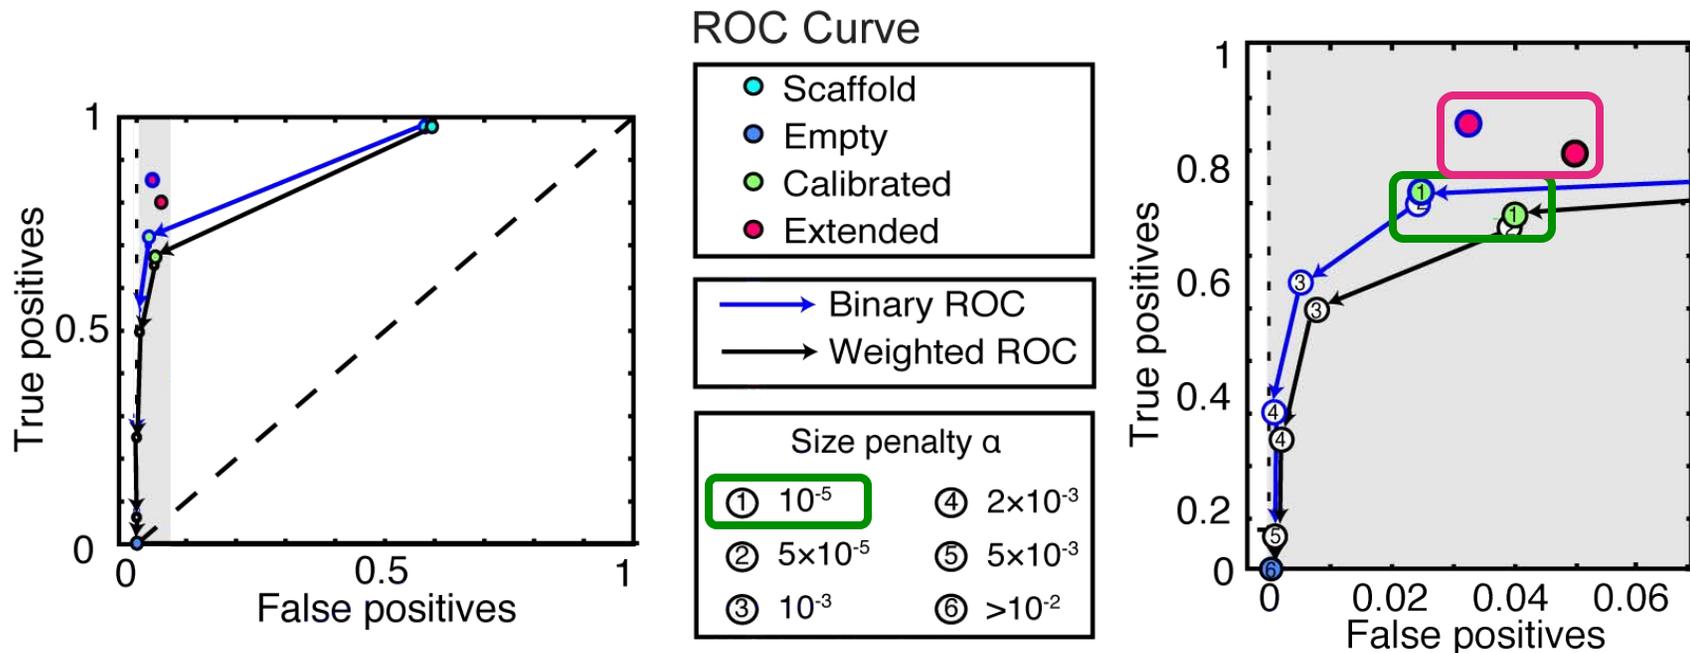

Frequency of Arc Distribution for Error Tolerance-Related (i.e., beyond exptl uncertainty) Model Families

© source unknown. All rights reserved. This content is excluded from our Creative Commons license. For more information, see <http://ocw.mit.edu/help/faq-fair-use/>.

Trade-off between False Negatives and False Positives

- Receiver Operating Characteristic (ROC) curve [ratio of true positives (1-false negatives) vs. false positives] for different values of the size penalty α
- Optimal choice of size penalty ($\alpha=10^{-5}$) corresponds to most predictive model
- Extended model (*i.e.*, with added arcs) decreases false negatives but increases false positives

© source unknown. All rights reserved. This content is excluded from our Creative Commons license. For more information, see <http://ocw.mit.edu/help/faq-fair-use/>.

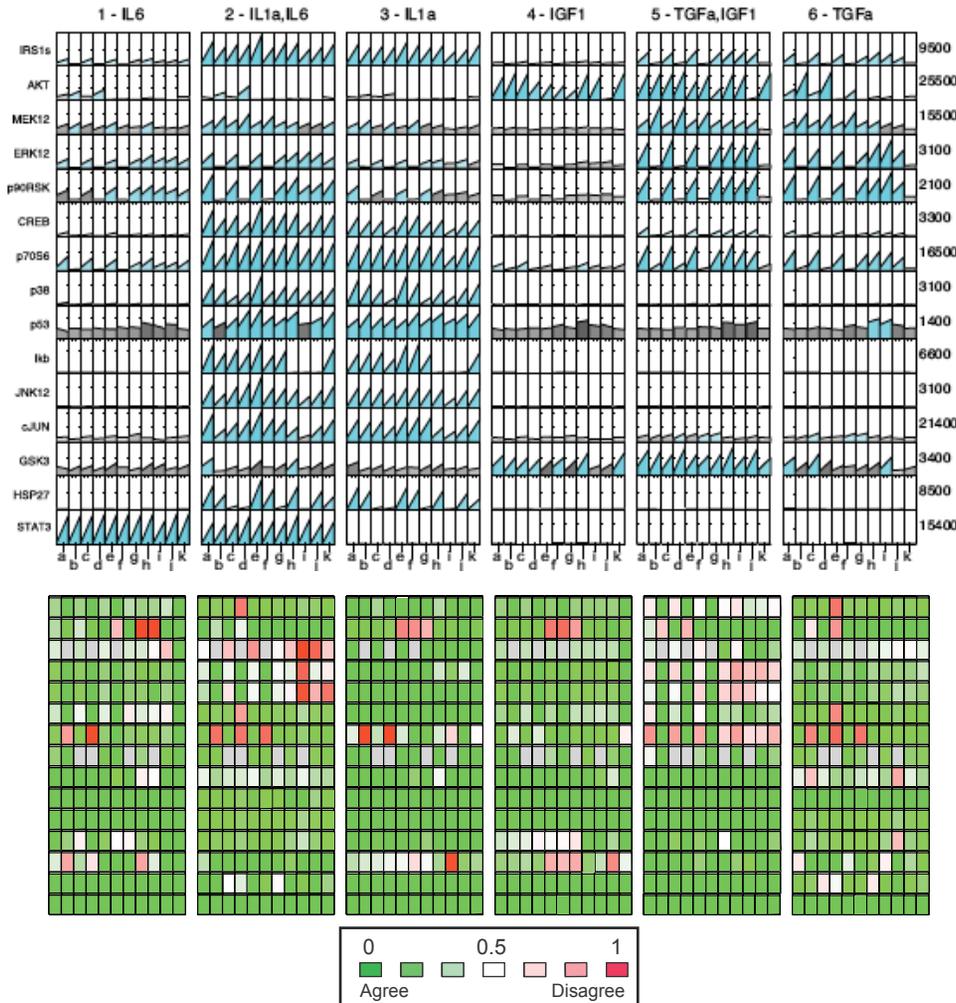

A

Experimental design

B

Validation data

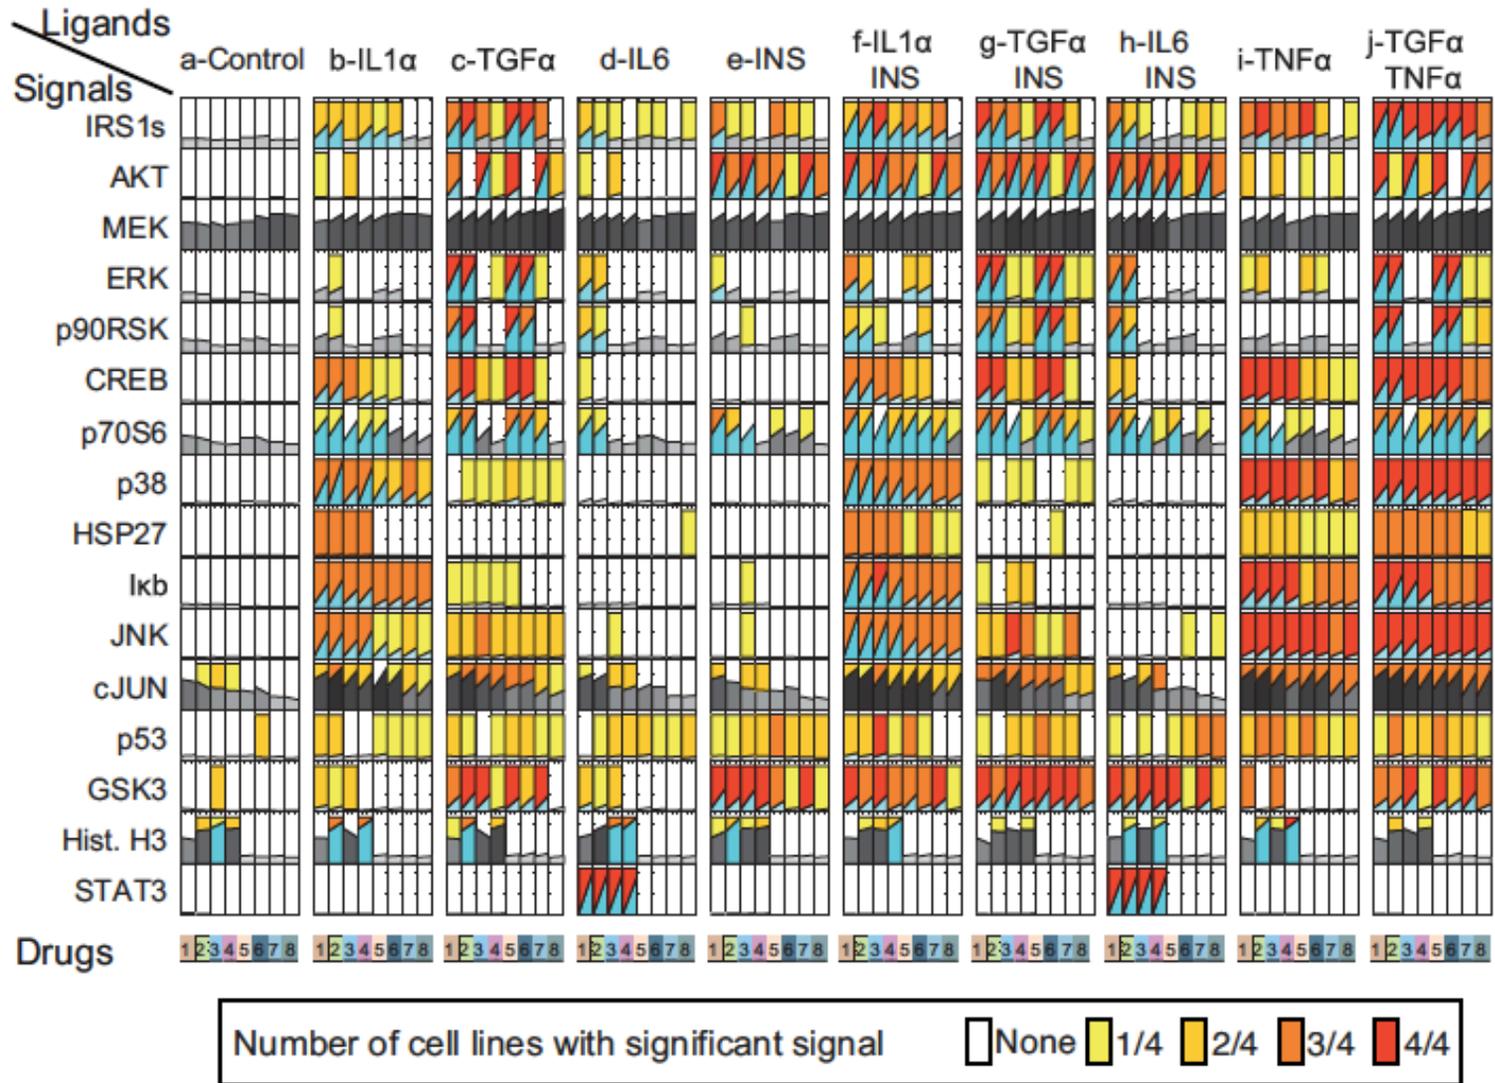

Model Validation

-- successful a priori predictions of new test data

- Used trained model to a priori predict effects of ligand combinations, additional inhibitors, and inhibitor combinations
- New test data predicted to within ~11% error, comparable to ~9% for original training data
- Can identify loci needing more detailed inquiry

Extension to comparison among hepatocellular lines -- phosphoproteomic data

Cancer Research 71, no. 16 (2011): 5400-11.

Best-Fit Boolean Logic Model Families for Primaries versus Lines

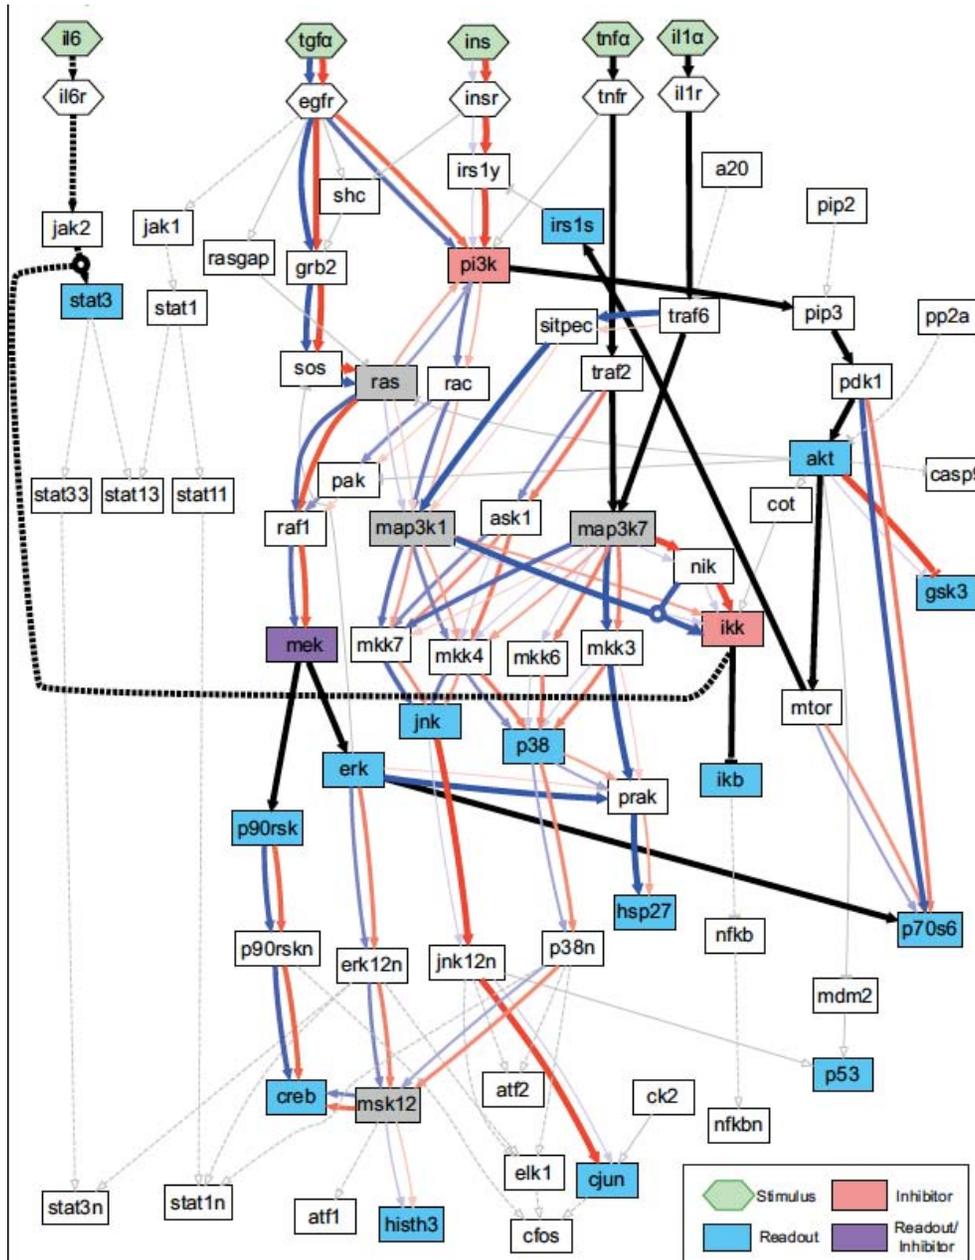

- Arc width corresponds to proportion of best-fit models bearing it
- Black arcs – all models in both primaries and HCC lines
- Blue arcs – most or all primary models
- Red arcs – most or all HCC line models
- Gray arcs deleted from original scaffold
- Dashed arc added to account for especially recalcitrant data

© American Association for Cancer Research. All rights reserved. This content is excluded from our Creative Commons license. For more information, see <http://ocw.mit.edu/help/faq-fair-use/>.

Source: Saez-Rodriguez, Julio, Leonidas G. Alexopoulos, et al. "Comparing Signaling Networks Between Normal and Transformed Hepatocytes Using Discrete Logical Models."

Cancer Research 71, no. 16 (2011): 5400-11.

Best-Fit Boolean Logic Model Families for Primaries versus Lines

- ~90% of original scaffold interactions were found in at least one best-fit model across families for all cell types
- but only <10% were found both in most primary cell models and cell line models
- multiple pathways are identifiable as dysregulated from normal to tumor lines

© American Association for Cancer Research. All rights reserved. This content is excluded from our Creative Commons license. For more information, see <http://ocw.mit.edu/help/faq-fair-use/>.

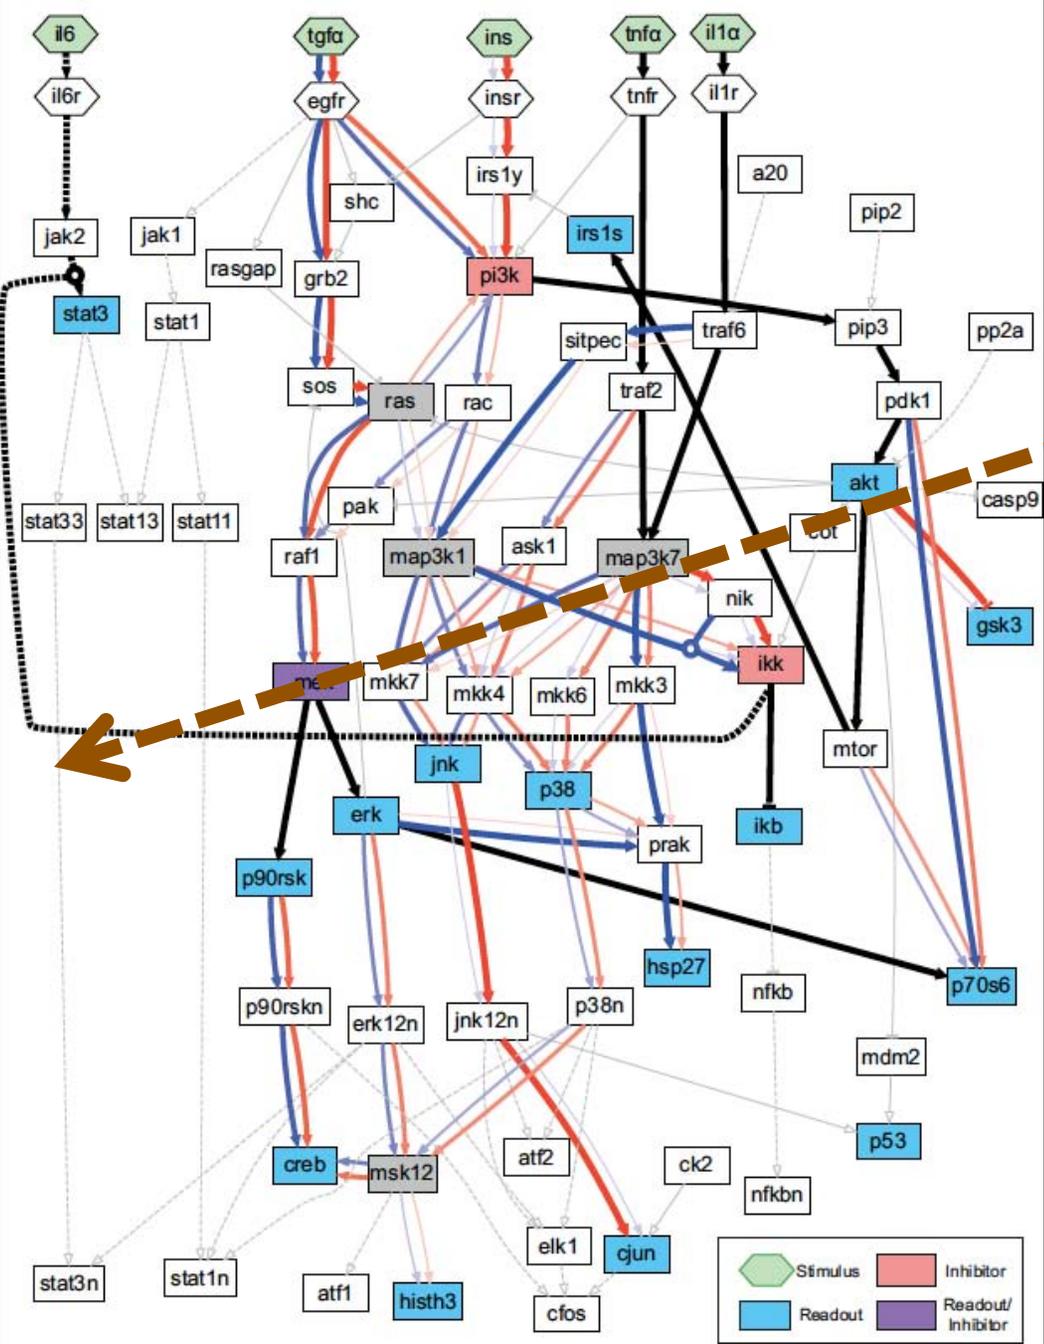

Source: Saez-Rodriguez, Julio, Leonidas G. Alexopoulos, et al. "Comparing Signaling Networks Between Normal and Transformed Hepatocytes Using Discrete Logical Models."

Cancer Research 71, no. 16 (2011): 5400-11.

Model permits novel insights concerning drug actions

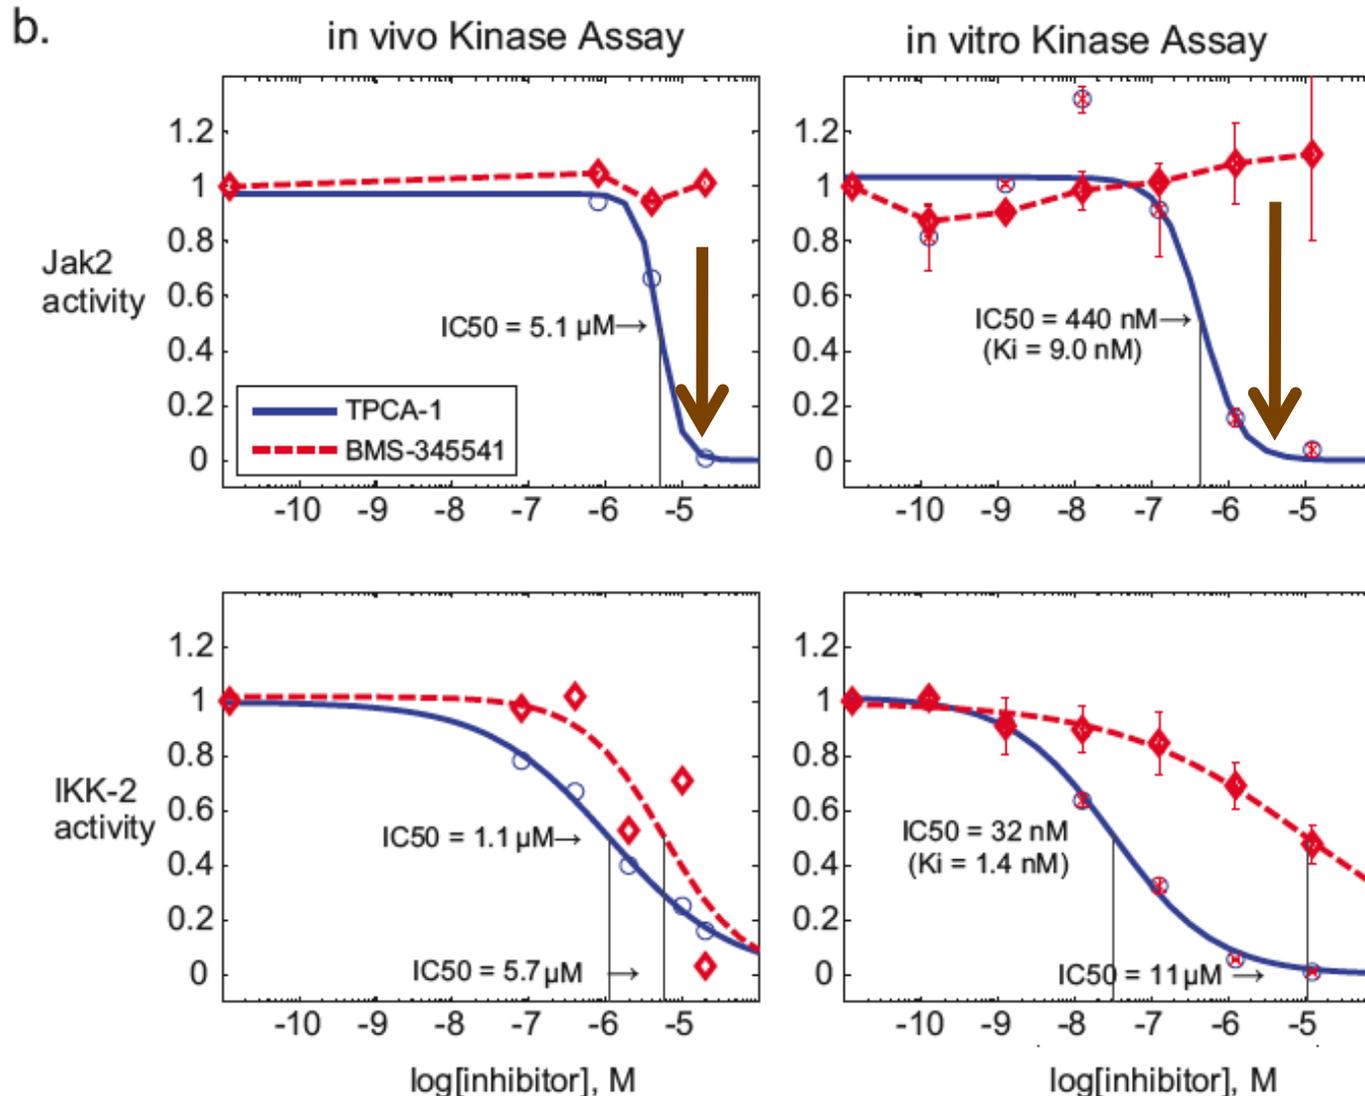

Dashed arc added to fit data generated in presence of IKK inhibitor TPCA1 – two potential explanations:

- IKK activity suppresses STAT3 activity downstream of JAK2;
- or
- TPCA1 has off-target effect on JAK2

© American Association for Cancer Research. All rights reserved. This content is excluded from our Creative Commons license. For more information, see <http://ocw.mit.edu/help/faq-fair-use/>. Source: Saez-Rodriguez, Julio, Leonidas G. Alexopoulos, et al. "Comparing Signaling Networks Between Normal and Transformed Hepatocytes Using Discrete Logical Models." *Cancer Research* 71, no. 16 (2011): 5400-11.

Experimental validation of model prediction that putative IKK inhibitor TPCA1 hits JAK2 as an off-target substrate (whereas BMS-345541 does not)

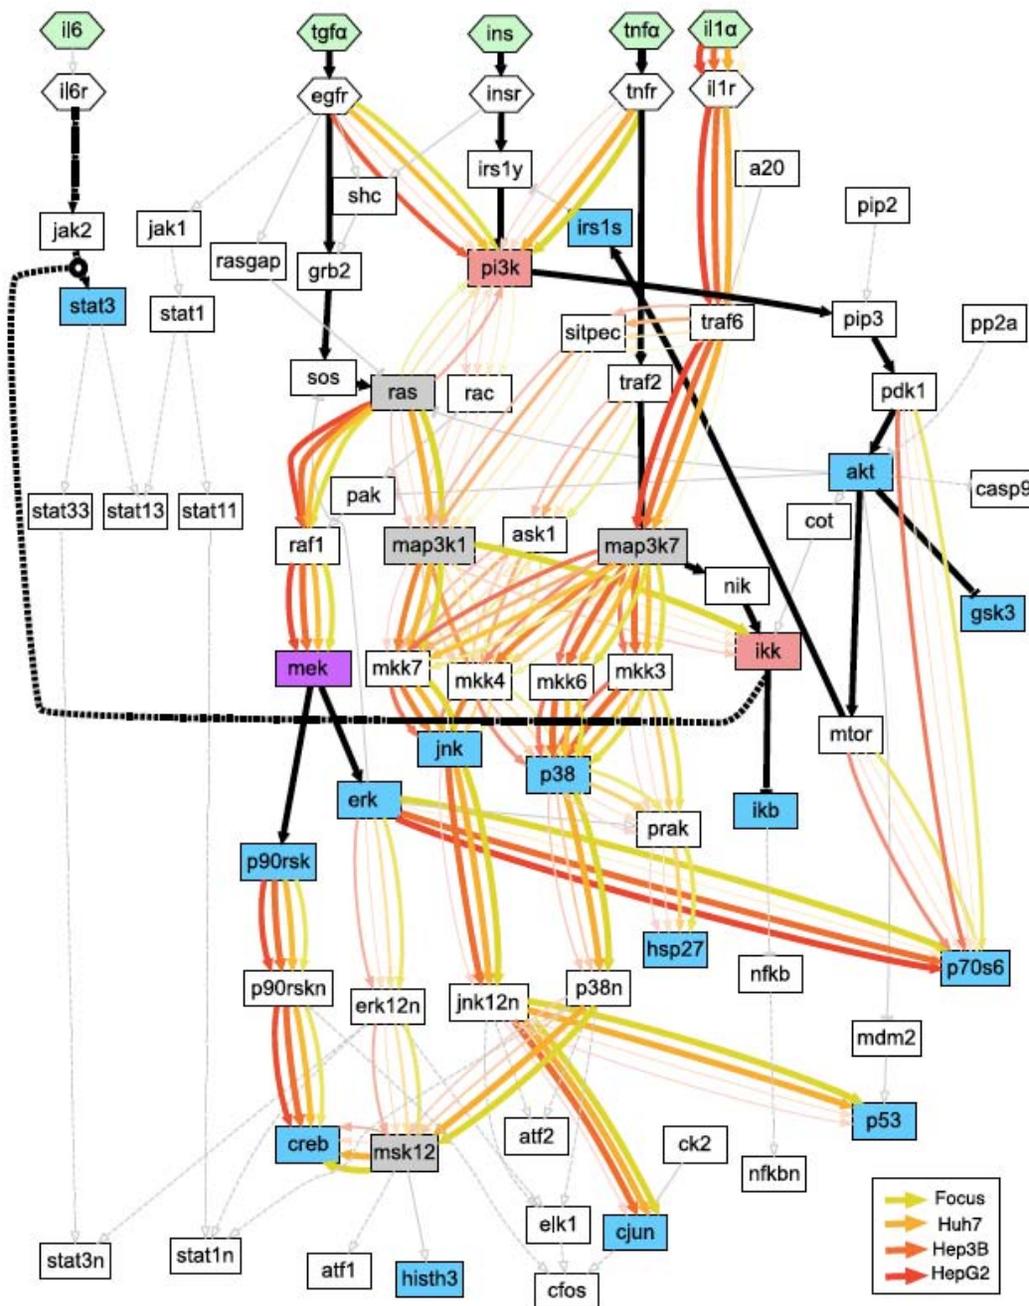

...perhaps providing an explanation for why TPCA1 has been found to be more efficacious for airway inflammation treatment than other IKK inhibitors

Best-Fit Boolean Logic Model Families

-- comparison among HCC Lines

- cell-type specificity of network operation is thus explicitly characterized – not only contrasting primaries to tumor lines but also disparities between different tumor lines

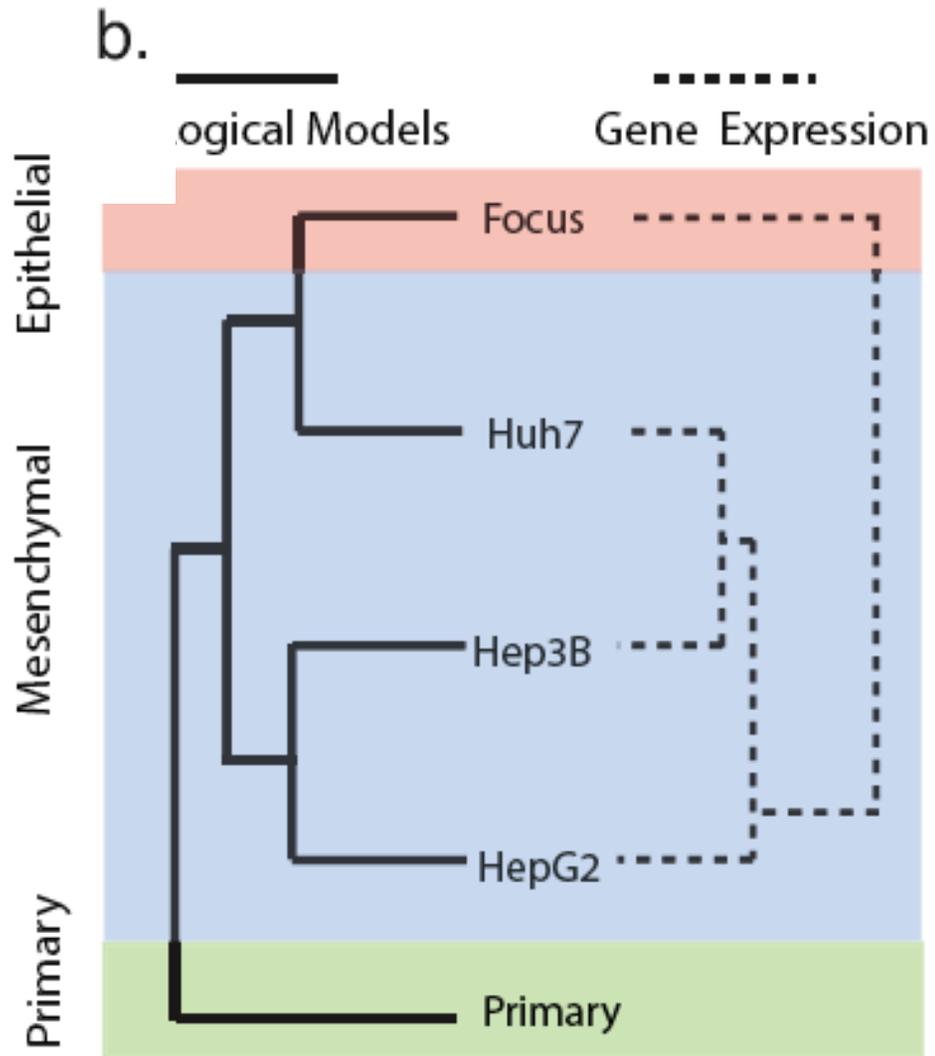

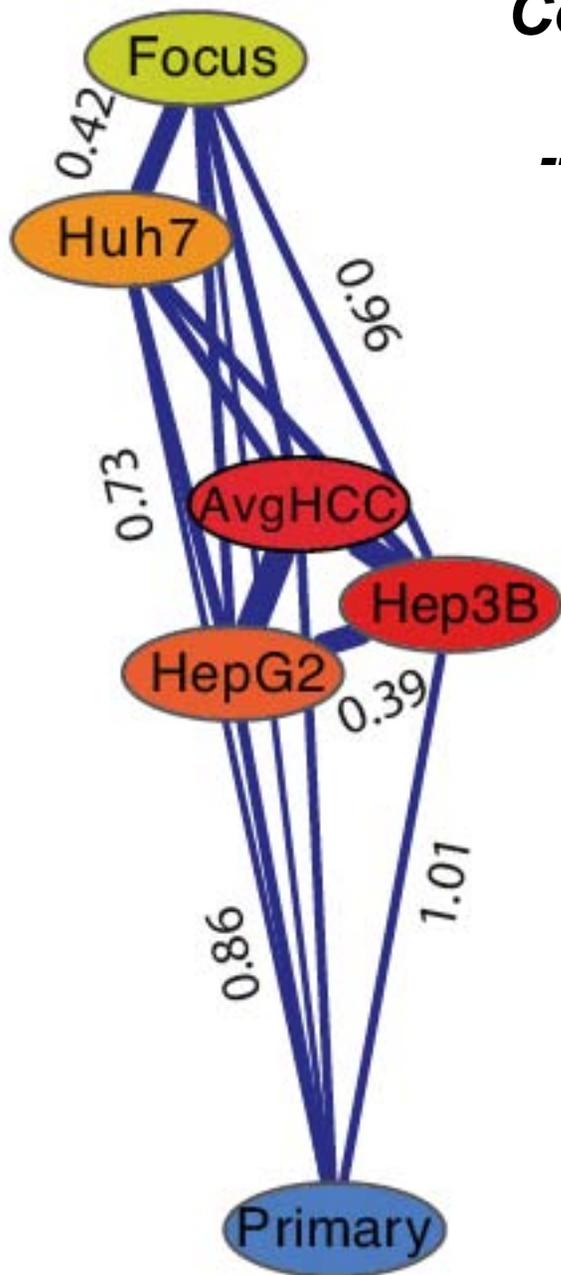

© American Association for Cancer Research. All rights reserved. This content is excluded from our Creative Commons license. For more information, see <http://ocw.mit.edu/help/faq-fair-use/>.

Source: Saez-Rodriguez, Julio, Leonidas G. Alexopoulos, et al. "Comparing Signaling Networks Between Normal and Transformed Hepatocytes Using Discrete Logical Models."

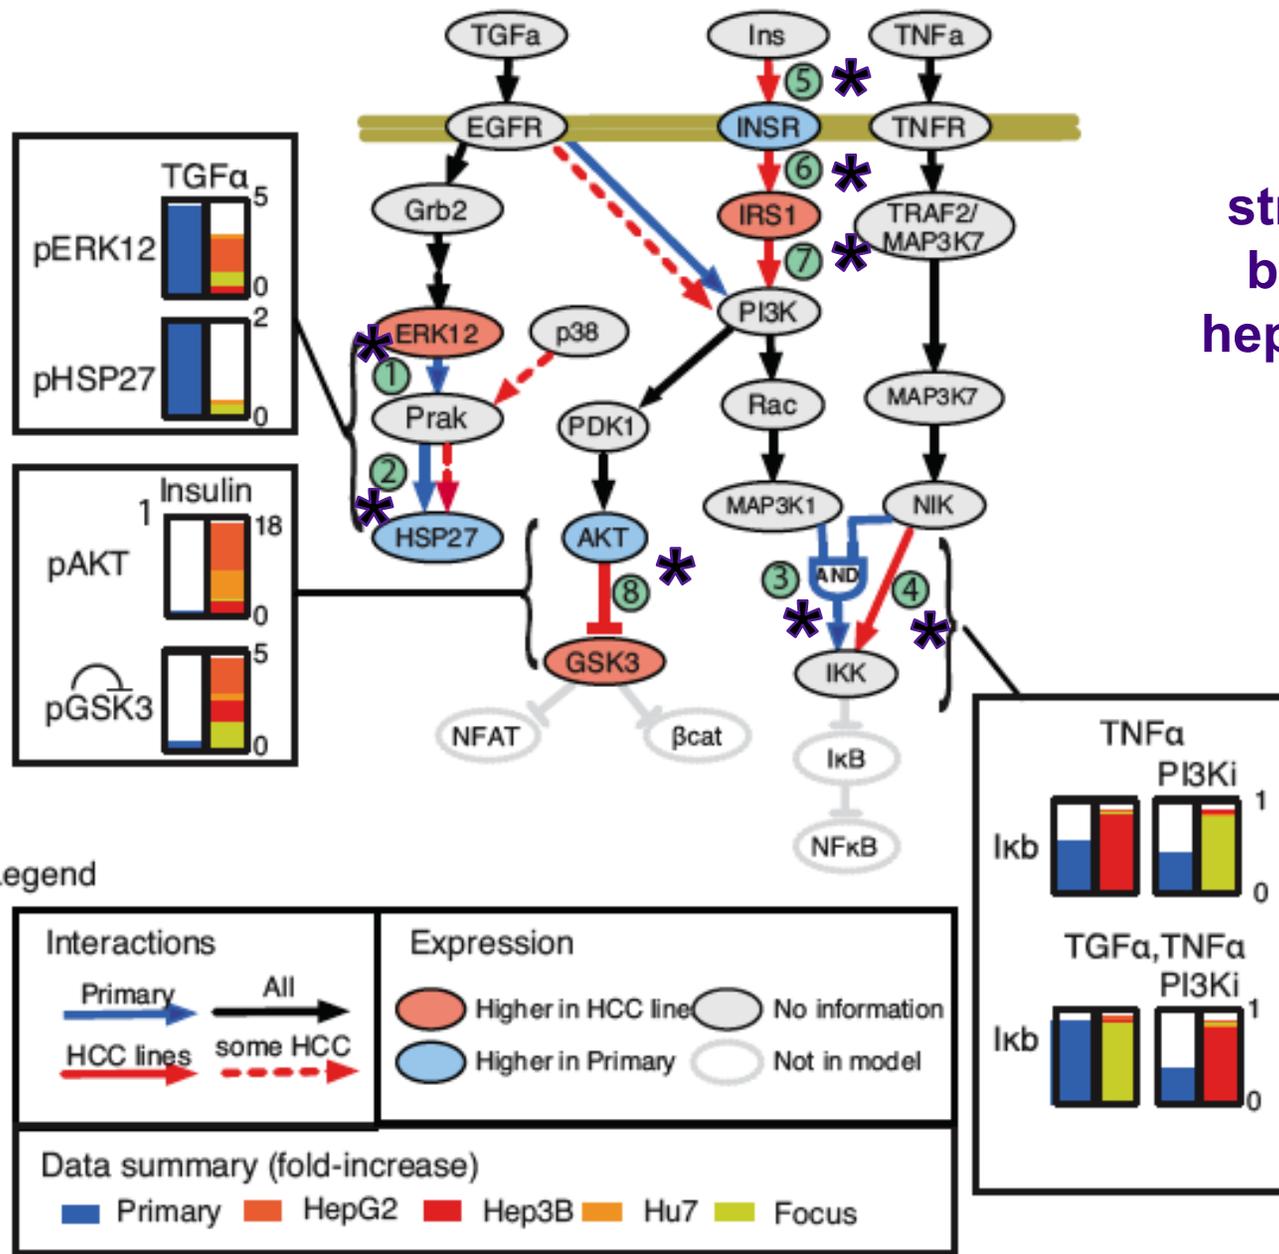

Cancer Research 71, no. 16 (2011): 5400-11.

Cell types can be quantitatively clustered with respect to common edges
-- reasonable similarity to transcriptomic result

© American Association for Cancer Research. All rights reserved. This content is excluded from our Creative Commons license. For more information, see <http://ocw.mit.edu/help/faq-fair-use/>.
 Source: Saez-Rodriguez, Julio, Leonidas G. Alexopoulos, et al. "Comparing Signaling Networks Between Normal and Transformed Hepatocytes Using Discrete Logical Models." *Cancer Research* 71, no. 16 (2011): 5400-11.

Detailed Primary-vs-Lines Comparison

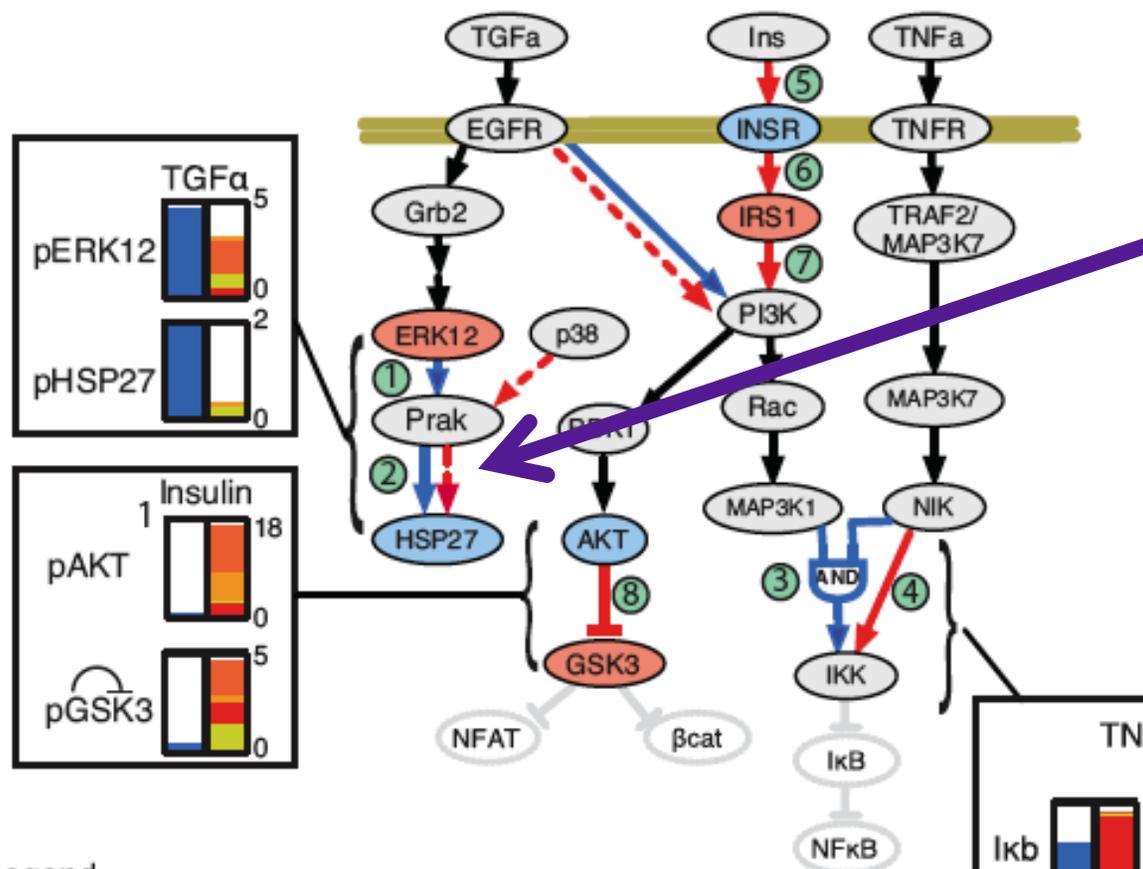

• 8 edges are strongly disparate between primary hepatocytes and the HCC lines

© American Association for Cancer Research. All rights reserved. This content is excluded from our Creative Commons license. For more information, see <http://ocw.mit.edu/help/faq-fair-use/>.

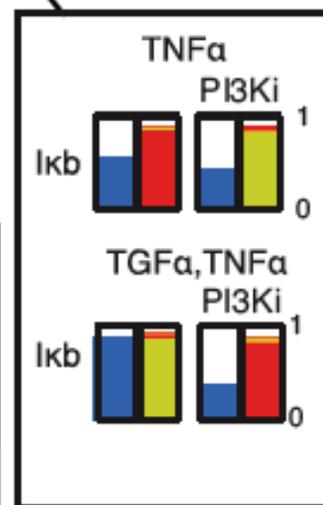

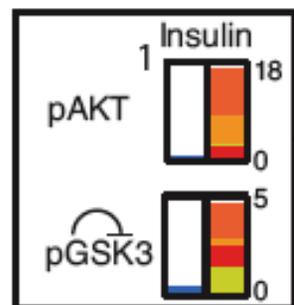

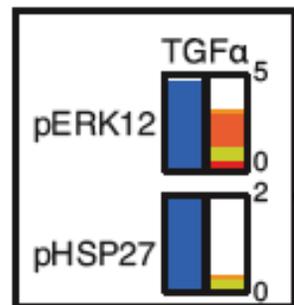

Source: Saez-Rodriguez, Julio, Leonidas G. Alexopoulos, et al. "Comparing Signaling Networks Between Normal and Transformed Hepatocytes Using Discrete Logical Models."

Cancer Research 71, no. 16 (2011): 5400-11.

Detailed Primary-vs-Lines Comparison – insights gained

- Whereas EGFR leads to ERK activation in all cell types, HSP27 is significantly activated downstream of ERK only in primaries
- In the lines, HSP27 was activated more mildly and via p38 instead of via ERK

(Literature: HCC tumor progression is associated with decreased HSP27 activation -- despite HSP27 over-expression)

Legend

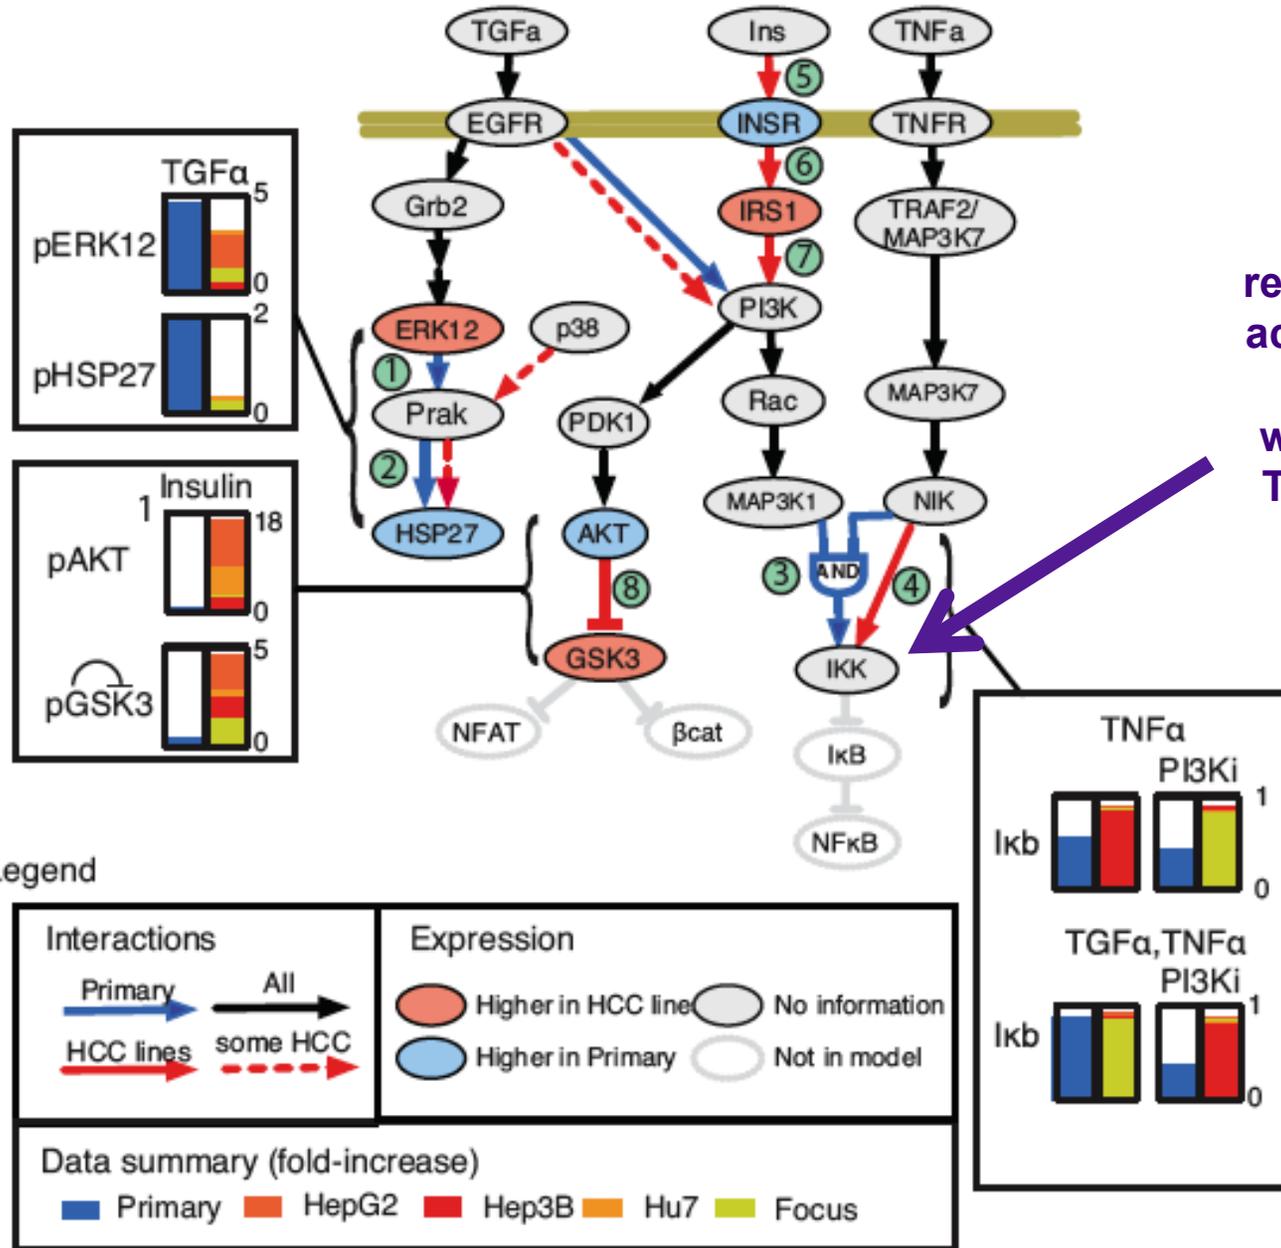

Interactions Primary → All HCC lines → some HCC	Expression Higher in HCC line (red circle) Higher in Primary (blue circle) No information (grey circle) Not in model (white circle)
Data summary (fold-increase) Primary (blue) HepG2 (orange) Hep3B (red) Hu7 (yellow) Focus (green)

Source: Saez-Rodriguez, Julio, Leonidas G. Alexopoulos, et al. "Comparing Signaling Networks Between Normal and Transformed Hepatocytes Using Discrete Logical Models."

Cancer Research 71, no. 16 (2011): 5400-11.

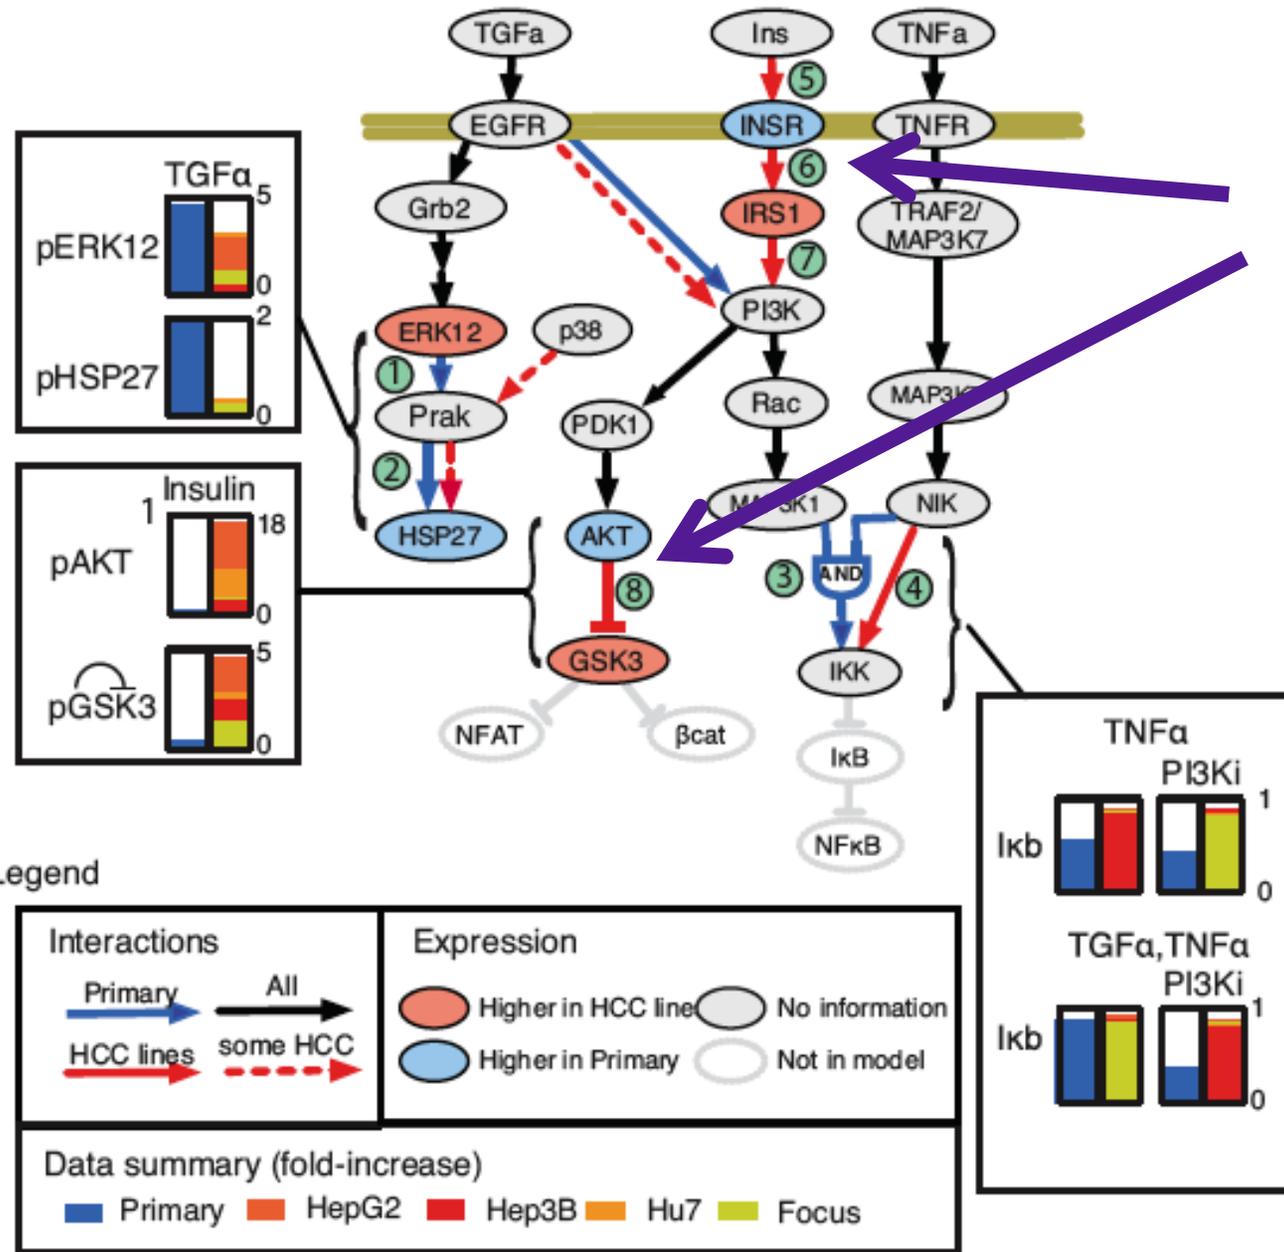

Detailed Primary-vs-Lines Comparison – insights gained

• In primaries Ikb phosphorylation requires TNFa-NIK and activation of PI3K-JNK (via TGFa or Ins), whereas in lines only TNFa-NIK is required

(Literature: HCC tumor progression is associated with looser control over NFkB-mediated survival signals)

Detailed Primary-vs-Lines Comparison – insights gained

• **GSK3** phosphorylation by Akt (leading to nuclear activation of pro-mitotic factors) is induced by Insulin in lines but not in primaries

(Literature: IRS1 is over-expressed in HCC, potentially shifting Insulin-induced signaling from IRS2-mediated metabolism to proliferation)
