IP OVERVIEW

Sources:

- Introduction to linear optimization
(Bertsimas, Tsitsiklis)- Chap 1
- Slides 1.224 Fall 2000

Outline

- When to use Integer Programming (IP)
- Binary Choices
 - Example: Warehouse Location
 - Example: Warehouse Location 2
- Restricted range of values
- Guidelines for strong formulation
- Set Partitioning models
- Solving the IP
 - Linear Programming relaxation
 - Branch-and bound
 - Example

When to use IP Formulation?

- IP (Integer Programming) vs. MIP (Mixed Integer Programming)
 - Binary integer program
- Greater modeling power than LP
- Allows to model:
 - Binary choices
 - Forcing constraints
 - Restricted range of values
 - Piecewise linear cost functions

Example: Warehouse Location

A company is considering opening warehouses in four cities: New York, Los Angeles, Chicago, and Atlanta. Each warehouse can ship 100 units per week. The weekly fixed cost of keeping each warehouse open is \$400 for New York, \$500 for LA, \$300 for Chicago, and \$150 for Atlanta. Region 1 requires 80 units per week, region 2 requires 70 units per week, and Region 3 requires 40 units per week. The shipping costs are shown below.

Formulate the problem to meet weekly demand at minimum cost.

From/To	Region 1	Region 2	Region 3
New York	20	40	50
Los Angeles	48	15	26
Chicago	26	35	18
Atlanta	24	50	35

Warehouse Location- Approach

- What are the decision variables?
 - Variables to represent whether or not to open a given warehouse ($y_i=0$ or 1)
 - Variables to track flows between warehouses and regions: x_{ij}
- What is the objective function?
 - Minimize (fixed costs+shipping costs)
- What are the constraints?
 - Constraint on flow out of each warehouse
 - Constraint on demand at each region
 - Constraint ensuring that flow out of a closed warehouse is 0.

Warehouse Location- Formulation

- Let y_i be the binary variable representing whether we open a warehouse i ($y_i=1$) or not ($y_i=0$).
- x_{ij} represents the flow from warehouse i to region j
- c_i = weekly cost of operating warehouse i
- t_{ij} = unit transportation cost from i to j
- W = the set of warehouses; R = the set of regions

$$\text{MIN} \left(\sum_{i \in W} c_i \cdot y_i + \sum_{i \in W} \sum_{j \in R} t_{ij} \cdot x_{ij} \right)$$

s.t.

$$\sum_j x_{ij} \leq 100 \cdot y_i, \forall i \in W$$

Forcing constraint

$$\sum_i x_{ij} = b_j, \forall j \in R$$

$$x_{ij} \in Z^+, y_i \in \{0,1\}$$

Warehouse Location- Additional Constraints

- If the New York warehouse is opened, the LA warehouse must be opened

$$y_{NYC} \leq y_{LA} \quad \text{Relationship constraint}$$

yNYC	yLA
1	1
0	1 or 0

- At most 2 warehouses can be opened

$$\sum_i y_i \leq 2 \quad \text{Relationship constraint}$$

- Either Atlanta or LA warehouse must be opened, but not both

$$y_{LA} + y_{ATL} = 1 \quad \text{Relationship constraint}$$

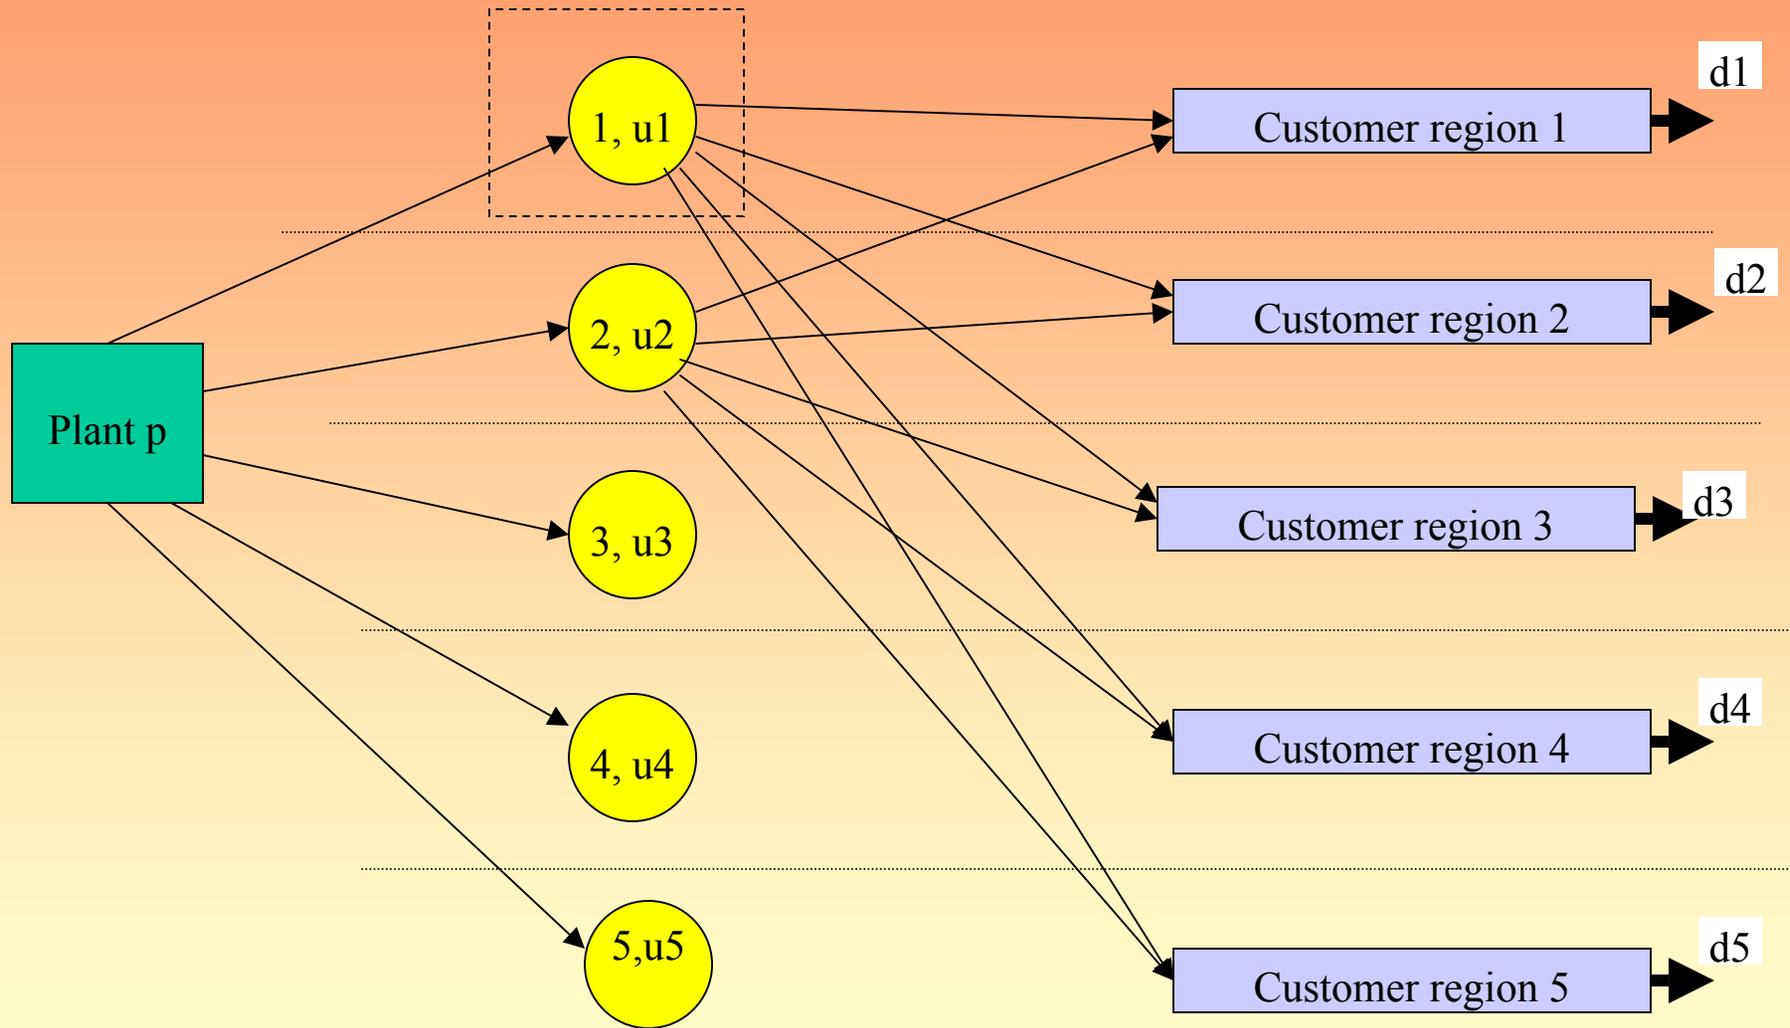

Binary Choices

- Model choice between 2 alternatives (open or closed, chosen or not, etc)
 - Set $x=0$ or $x=1$ depending on the chosen alternative
- Can model fixed or set-up costs for a warehouse
- Forcing flow constraints
 - if warehouse is not open, no flow can come out of it
- Can model relationships

Example: Warehouse Location 2

- A company is looking at adding one or more warehouses somewhere in the R regions which they serve. Each warehouse costs $\$c_w$ per month to operate and can deliver a total of u_w units per month. It costs $\$c_{ij}$ to transport a unit from the plant in region i to the warehouse in region j . Furthermore, the delivery costs from a warehouse in region j to consumers in region j is zero. Warehouses can service other regions, but the company must pay additional transportation costs of $\$t$ per unit per additional region crossed. So to deliver 1 unit from a warehouse in region 2 to a customer in region 4 would cost $\$(2 \cdot t)$. Note that the cost to transport a good from warehouse 0 to warehouse R is $\$(R \cdot t)$, not $\$t$. All units must travel through a warehouse on their way to the customer. Finally, there is a monthly demand for d_j units of the product in region j . Formulate the problem to determine where to locate the new warehouses so as to minimize the total cost each month if the plant is located in region p .

Example 2: Network Representation

Example 2: Approach

- Decision Variables?
 - y_i = whether or not we open a warehouse in region i
 - z_{ij} = flow from warehouse i to region j
 - x_{pj} = flow from plant p to warehouse j .
- Objective Function?
 - MIN (fixed costs + transportation costs from plant to warehouse + transportation costs from warehouse to region)
- Constraints?
 - balance constraints at each warehouse
 - demand constraints for each region
 - capacity constraints at each warehouse.
- Let a_{ij} = cost of delivering a unit from warehouse i to region j , $a_{ij} = t \cdot |j - i|$
- Let c_{pj} = cost of transporting one unit from the plant to warehouse j

Example 2: Formulation

$$\text{Min } \sum_{i \in R} c_w \cdot y_i + \sum_{j \in R} c_{pj} x_{pj} + \sum_{i \in R} \sum_{j \in R} a_{ij} \cdot z_{ij}$$

s.t.

$$\sum_{i \in R} z_{ij} = d_j, \forall j \in R$$

$$\sum_{j \in R} z_{ij} - x_{pi} = 0, \forall i \in R$$

$$x_{pi} \leq u_w y_i, \forall i \in R$$

$$x_{ij}, z_{ij} \in Z^+ \forall i, j \in R; y_i \in \{0,1\} \forall i \in R$$

Example 2: Additional Constraints

- At most 3 warehouses can be opened

$$\sum_{i \in R} y_i \leq 3$$

- If you open a warehouse in some region r_{w1} or r_{w2} , you must also open a warehouse in region r_{w3}

$$y_{rw3} \geq y_{rw1}$$

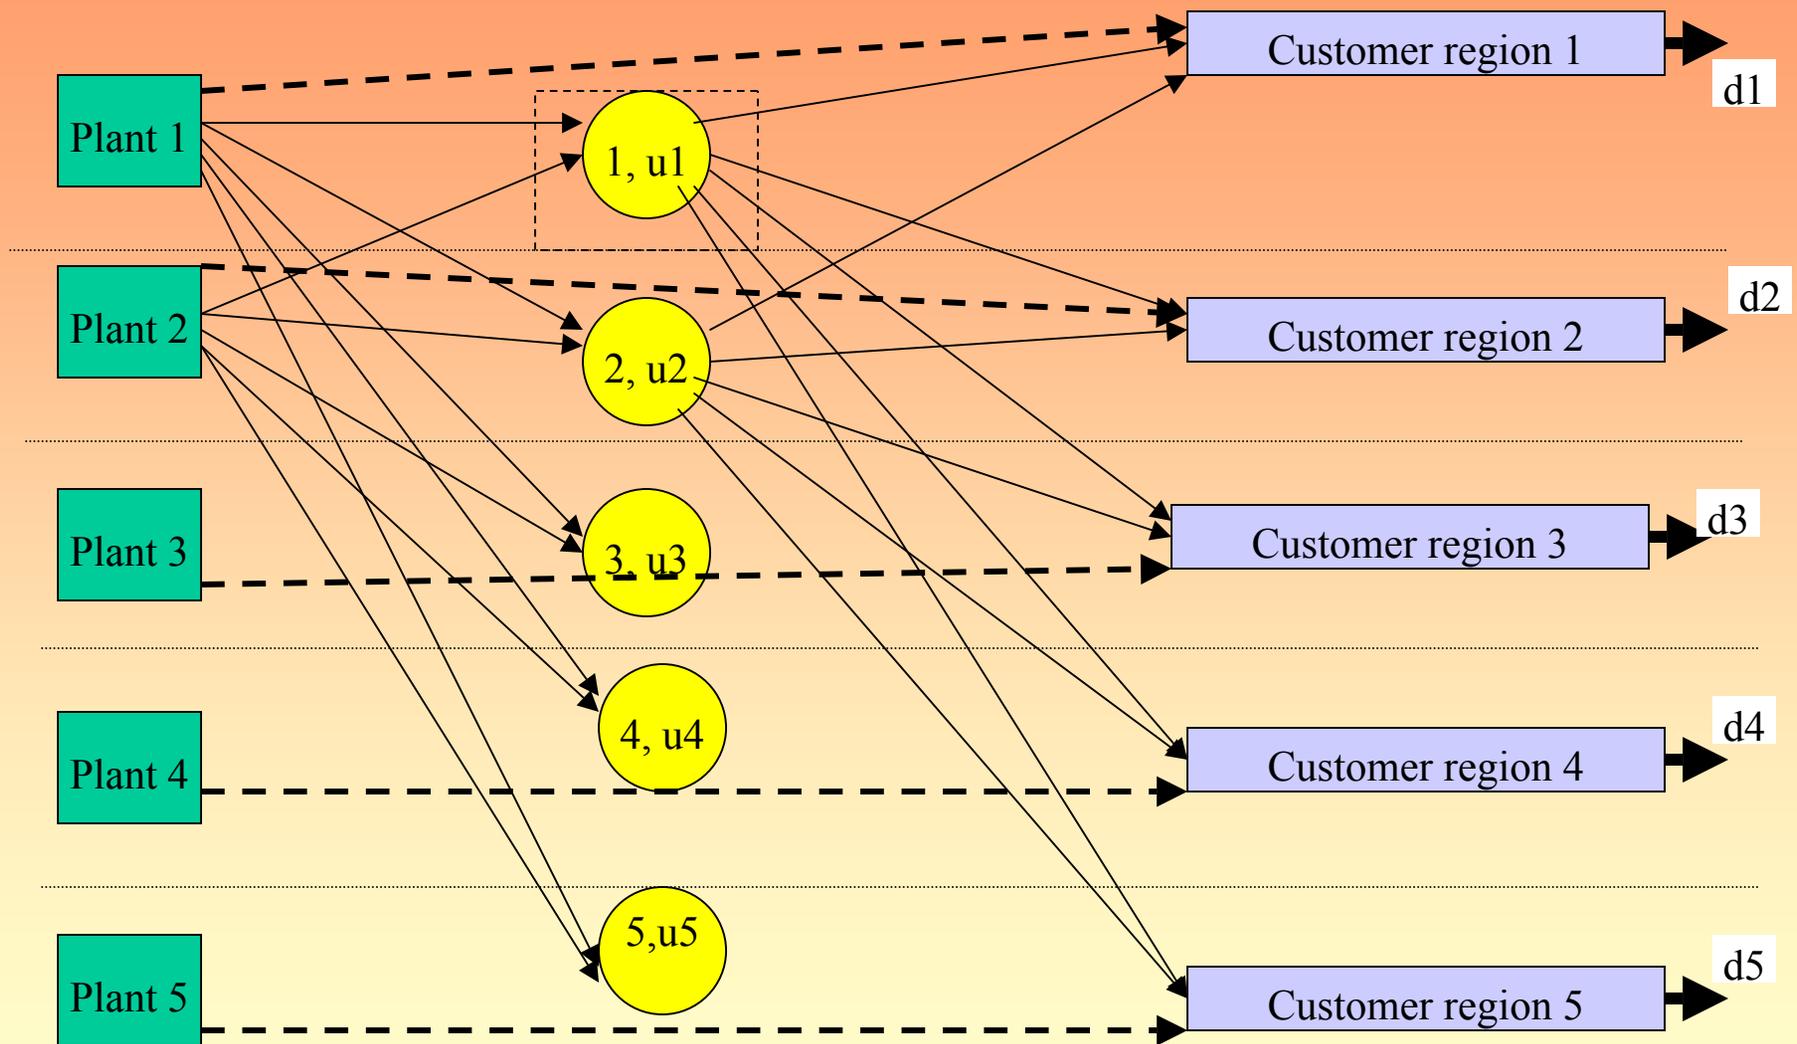

$$y_{rw3} \geq y_{rw2}$$

yrw1	yrw2	yrw3
1	0	1
0	1	1
1	1	1
0	0	0 or 1

Example 2: Additional Constraints

- A plant costs $\$c_p$ per month to operate and can output u_p units per month. In this case, a plant can deliver directly to customers in its region at no additional cost, however it cannot deliver directly to customers in other regions; all units traveling out of the plant's region must pass through a warehouse before their delivery to the customer. Formulate the problem to find the optimal distribution of plants and warehouses.
- Additional decision variables:
 - w_i = whether or not we open a plant in region i
 - u_i = amount of flow directly from plant i to region i (no cost)
- Objective Function
 - Additional term to account for the cost of the plants
- Revised constraints
 - Constraints range over all regions, not only region p
 - Add direct flow from plant to customers in same region
 - Add constraint that total flow leaving a plant is less than u_p

Example 2: Network Representation 2

Example 2: Formulation 2

$$\text{MIN} \sum_{i \in R} c_w \cdot y_i + \sum_{i \in R} c_p \cdot w_i + \sum_{i \in R} \sum_{j \in R} c_{ij} \cdot x_{ij} + \sum_{i \in R} \sum_{j \in R} a_{ij} \cdot z_{ij}$$

s.t

$$\sum_{i \in R} z_{ij} + u_j = d_j, \forall j \in R$$

$$\sum_{j \in R} z_{ij} - \sum_{j \in R} x_{ji} = 0, \forall i \in R$$

$$\sum_{j \in R} x_{ji} \leq u_w \cdot y_i, \forall i \in R$$

$$\sum_{j \in R} x_{ij} + u_i \leq u_p \cdot w_i, \forall i \in R$$

$$u_i, x_{ij}, z_{ij} \in Z^+ \forall i, j \in R; w_i, y_i \in \{0,1\} \forall i \in R$$

Restricted range of values

- Restrict a variable x to take values in a set $\{a_1, \dots, a_m\}$
- Introduce m binary variables $y_j, j=1..m$ and the constraints

$$X = \sum_{j=1..m} a_j y_j$$

s.t.

$$\sum_{j=1..m} y_j = 1$$

$$y_j \in \{0,1\}, \forall j$$

Guidelines for strong formulation

- Good formulation in LP: small number of variables (n) and constraints (m), because computational complexity of problem grows polynomially in n and m
- LP: choice of a formulation is important but does not critically affect ability to solve the problem
- IP: Choice of formulation is crucial!
- Example: aggregation of demand (Warehouse)

Set Partitioning models

- Very easy to write, often very hard to solve
- All rules, even non-linear, impractical rules can be respected
- Every object is in exactly one set
- Huge number of variables (all feasible combinations)

Linear Programming relaxation

- Relax the integrality constraint
- Examples:
 - X_j in Z^+ becomes $X_j \geq 0$
 - X_j in $\{0,1\}$ becomes $0 \leq X_j \leq 1$
- If an optimal solution to the relaxation is feasible for the MIP (i.e., X take on integer values in the optimal solution of the relaxation) \Rightarrow it is also the optimal solution to the MIP
- The LP relaxation provides a lower bound on the solution of the IP
- Good formulations provide a “tight” bound on the IP

Branch-and-Bounds: A solution approach for binary Integer programs

- Branch-and-bound is a smart enumeration strategy:
 - With branching, all possible solutions are enumerated (e.g. $2^{\text{number of binary variables}}$)
 - With bounding, only a (usually) small subset of possible solutions are evaluated before a provably optimal solution is found

Branch-and-Bound Algorithm

Beginning with root node (minimization):

- Bound:
 - Solve the current LP with this and all restrictions along the (back) path to the root node enforced
- Prune
 - If optimal LP value is greater than or equal to the incumbent solution \Rightarrow Prune
 - If LP is infeasible \Rightarrow Prune
 - If LP is integral \Rightarrow Prune
- Branch
 - Set some variable to an integer value
- Repeat until all nodes pruned

Example

Company XYZ produces products A, B, C and D. In order to manufacture these products, Company XYZ needs:

	A	B	C	D	Availability
Profit	2	1.8	1.82	1.9	
Nails	10	8	9	10	30
Screws	5	6	4	4	15
Glue	1.1	1.1	0.9	1	3.5

- Company XYZ wants to know which products it should manufacture.
- Let $X_p = 1$ if product P is manufactured, 0 otherwise

Solving the LP

The screenshot displays the OPL Studio interface for solving a linear programming problem. The main window shows the model code, and the console window shows the optimal solution.

```
constraint cst[1..3];  
  
/* Enter coefficients*/  
float+ A[1..3,1..4]= [[10, 8,9,10], [5,6,4,4],[1.1,1.1,0.9,1]];  
float C[1..4]=[-2,-1.8,-1.82,-1.9];  
float+ b[1..3]=[30, 15,3.5];  
  
/* Define variable as a positive float*/  
var float+ X[1..4];  
/*var int X[1..2] in 0..1;*/  
  
minimize sum(j in 1..4) C[j]*X[j]  
subject to{  
forall (i in 1..3)  
cst[i]: sum(j in 1..4) A[i,j]*X[j] <=b[i];  
forall (j in 1..4) X[j]<=1;  
};  
display (j in 1..4) X[j];  
display (j in 1..4) X[j].rc; /* display reduced costs*/  
display (i in 1..3) cst[i].dual; /*display dual values*/
```

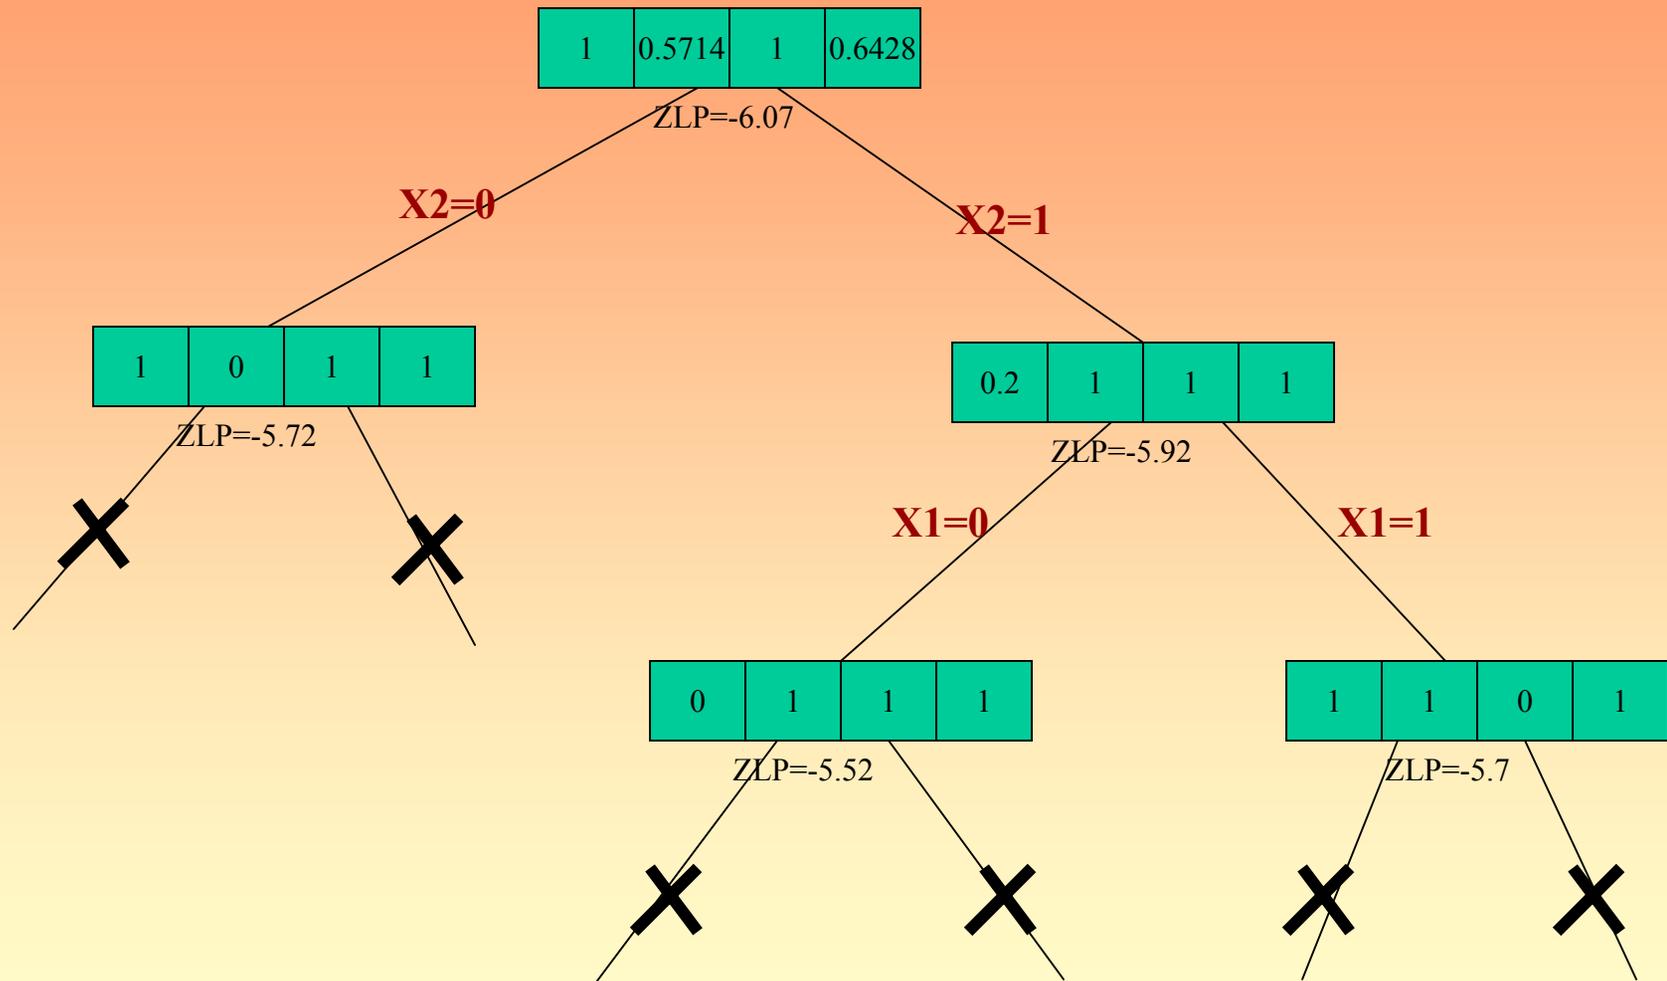

Optimal Solution with Objective Value: -6.0700
X[1] = 1.0000
X[2] = 0.5714
X[3] = 1.0000
X[4] = 0.6428
