

# MACRO DESIGN MODELS FOR A SINGLE ROUTE

## Outline

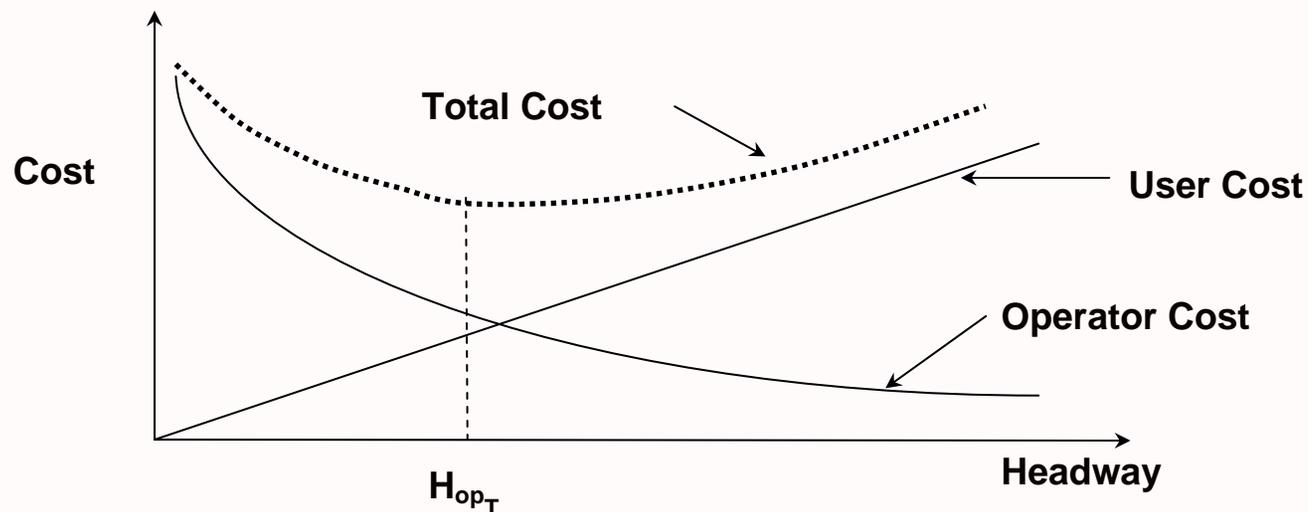

1. Introduction to analysis approach
2. Bus frequency model
3. Bus size model
4. Stop/station spacing model

# Introduction to Analysis Approach

- **Basic approach is to establish an aggregate total cost function including:**
  - operator cost as  $f$  (design parameters)
  - user cost as  $g$  (design parameters)
- **Minimize total cost function to determine optimal design parameter (s.t. constraints)**

**Variants include:**

- **Maximize service quality s.t. budget constraint**
- **Maximize consumer surplus s.t. budget constraint**

# Bus Frequency Model: the Square Root Model

**Problem: define bus service frequency on a route as a function of ridership**

**Total Cost = operator cost + user cost**

$$Z = c \cdot \frac{t}{h} + b \cdot r \cdot \frac{h}{2}$$

where  $Z$  = total (operator + user) cost per unit time  
 $c$  = operating cost per unit time  
 $t$  = round trip time  
 $h$  = headway – the decision variable to be determined  
 $b$  = value of unit passenger waiting time  
 $r$  = ridership per unit time

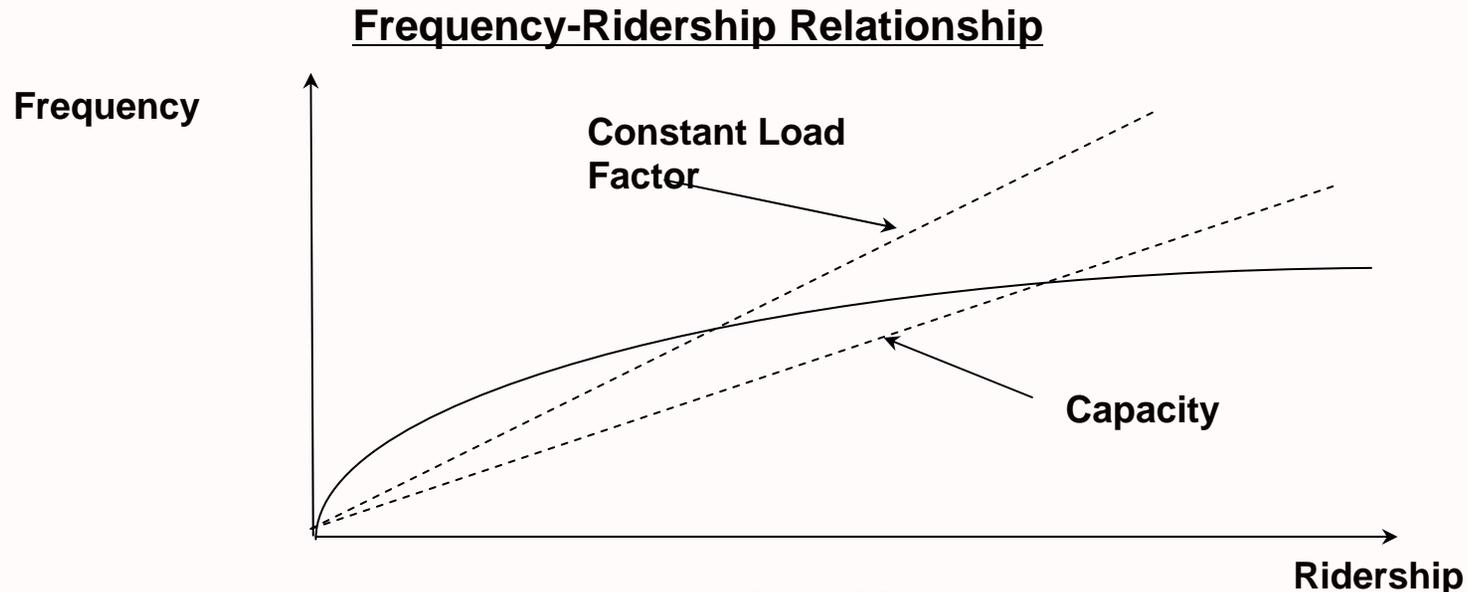

Minimizing  $Z$  w.r.t.  $h$  yields :

$$h = \sqrt{\frac{2ct}{br}} \text{ or } \sqrt{2 \left(\frac{c}{b}\right) \left(\frac{t}{r}\right)}$$

# Square Root Model (cont'd)

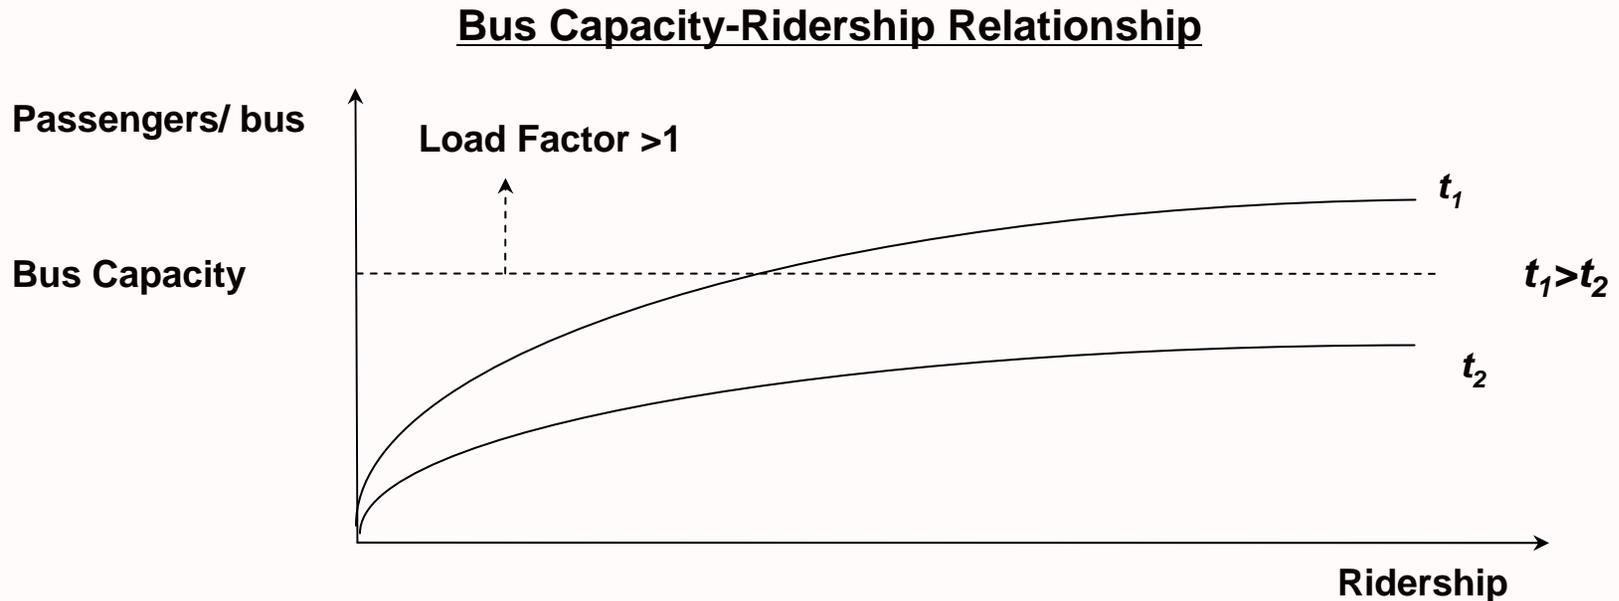

This is the Square Rule with the following implications:

- high frequency is appropriate where (cost of wait time/cost of operations time) is high
- frequency is proportional to the square root of ridership per unit time for routes of similar length

# Square Root Model (cont'd)

- Load factor is proportional to the square root of the product of ridership and route length.

# Square Root Model (cont'd)

## Critical Assumptions:

- bus capacity is never binding
- only frequency benefits are wait time savings
- ridership  $\neq f$  (frequency)
- simple wait time model
- budget constraint is not binding

## Possible Remedies:

- introduce bus capacity constraint
- modify objective function
- introduce  $r=f(h)$  and re-define objective function
- modify objective function
- introduce budget constraint

# Bus Frequency Example

If:       $c = \$90/\text{bus hour}$   
          $b = \$10/\text{passenger hour}$   
          $t = 90 \text{ mins}$   
          $r = 1,000 \text{ passengers/hour}$

Then:  $h_{OPT} = 11 \text{ mins}$

# Bus Size Model

**Problem: define optimal bus size on a route**

**Assumptions:**

- Desired load factor is constant
- Labor cost/bus hour is independent of bus size
- Non-labor costs are proportional to bus size
- Bus dwell time costs per passenger are independent of bus size

**Using same notation as before plus:**

**$w$  = labor cost per bus hour**

**$p$  = passenger flow past peak load point**

**$k$  = desired bus load - the decision variable to be determined**

$$\text{Then } Z = w \cdot \frac{t}{h} + b \cdot r \cdot \frac{h}{2}$$

$$\text{Now } h = \frac{k}{p} \text{ by assumption above}$$

$$\therefore Z = \frac{wtp}{k} + \frac{brk}{2p}$$

$$\text{Minimizing } Z \text{ w.r.t. } k \text{ gives: } k_{OPT} = \sqrt{\frac{2p^2wt}{rb}}$$

# Bus Size Model (cont'd)

**Result is another square root model, implying that optimal bus size increases with:**

- round trip time
- ratio of labor cost to passenger wait time cost
- peak passenger flow
- concentration of passenger flows

**Previous example extended with:**

$p = 500$  pass/hour

$w = \$40$ /bus hour

all other parameters as before:

**Then:  $h_{OPT} = 55$**

# Stop/Station Spacing Model

**Problem: determine optimal stop or station spacing**

**Trade-off is between walk access time (which increases with station spacing), and in-vehicle time (which decreases as station spacing increases) for the user, and operating cost (which decreases as station spacing increases)**

<b>Define</b>	<b><math>Z</math></b>	<b>=</b>	<b>total cost per unit distance along route and per headway</b>
<b>and</b>	<b><math>T_{st}</math></b>	<b>=</b>	<b>time lost by vehicle making a stop</b>
	<b><math>c</math></b>	<b>=</b>	<b>vehicle operating cost per unit time</b>
	<b><math>s</math></b>	<b>=</b>	<b>station/stop spacing - the decision variable to be determined</b>
	<b><math>N</math></b>	<b>=</b>	<b>number of passengers on board vehicle</b>
	<b><math>v</math></b>	<b>=</b>	<b>value of passenger in-vehicle time</b>
	<b><math>D</math></b>	<b>=</b>	<b>demand density in passenger per unit route length per headway</b>
	<b><math>V_{acc}</math></b>	<b>=</b>	<b>value of passenger access time</b>
	<b><math>w</math></b>	<b>=</b>	<b>walk speed</b>
	<b><math>c_s</math></b>	<b>=</b>	<b>station/stop cost per headway</b>

# Stop/Station Spacing Model (cont'd)

$$Z = \frac{T_{st}}{s} (c + N \cdot v) + \frac{c_s}{s} + \frac{s}{4} \cdot D \cdot \frac{v_{acc}}{w}$$

Minimizing  $Z$  w.r.t.  $s$  gives :

$$s_{OPT} = \left[ \frac{4w}{Dv_{acc}} [c_s + T_{st}(c_v + Nv)] \right]^{1/2}$$

**Yet another square root relationship, implying that station/stop spacing increases with:**

- **walk speed**
- **station/stop cost**
- **time lost per stop**
- **vehicle operating cost**
- **number of passengers on board vehicle**
- **value of in-vehicle time**

**and decreases with:**

- **demand density**
- **value of access time**

# Bus Stop Spacing

## *U.S. Practice*

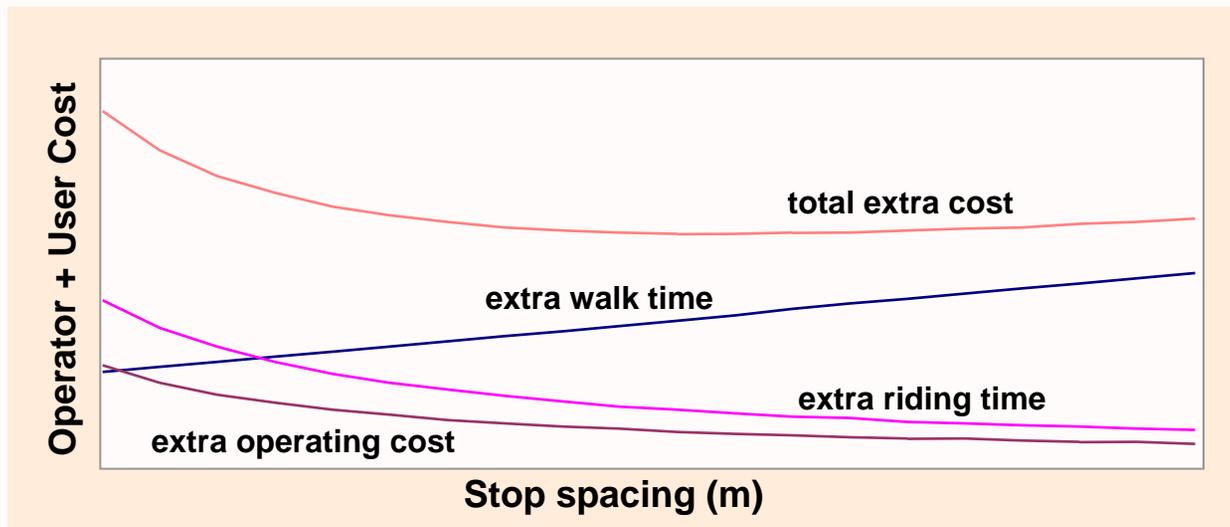

- 200 m between stops (8 per mile)
- shelters are rare
- little or no schedule information

## *European Practice*

- 320 m between stops (5 per mile)
- named & sheltered
- up to date schedule information
- scheduled time for every stop

# Stop Spacing Tradeoffs

- Walking time
- Riding time
- Operating cost
- Ride quality

# Walk Access: Block-Level Modeling

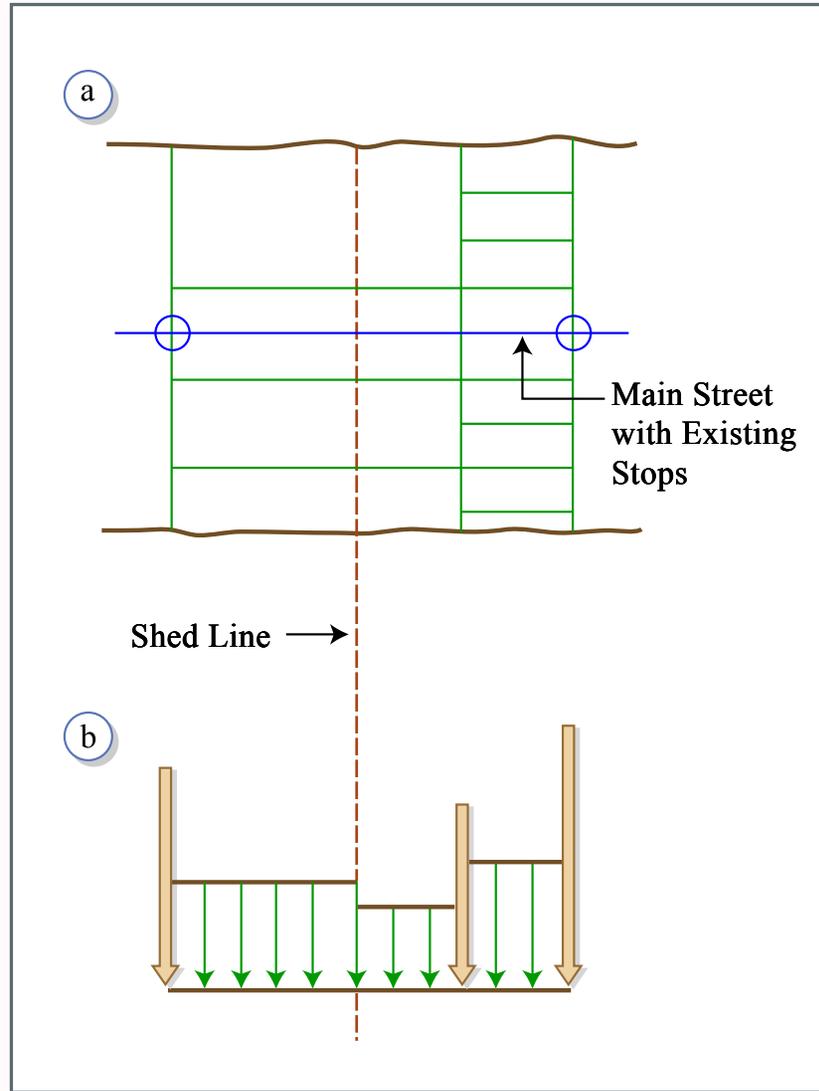

Figure by MIT OpenCourseWare.

# Results: MBTA Route 39\*

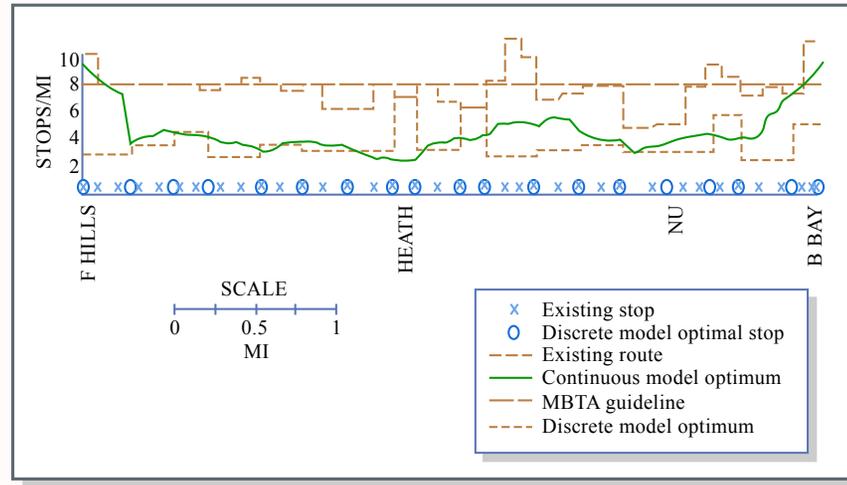

Figure by MIT OpenCourseWare.

## AM Peak Inbound results

- Avg walking time up 40 s
- Avg riding time down 110 s
- Running time down 4.2 min
- Save 1, maybe 2 buses

# Bus Stop Locations and Policies

- **Far-side (vs. Near-side)**
  - less queue interference
  - easier pull-in
  - fewer ped conflicts
  - snowbank problem demands priority in maintenance
- **Curb extensions benefit transit, peds, and traffic (0.9 min/mi speed increase)**
- **Pull-out priority (it's the law in some states)**
- **Reducing dwell time (vehicle design, fare collection, fare policy)**
