Problem Set 1

Spring 2006

Due February 23

- 1) An infinitely long cylinder with a diameter of 10 cm is filled with a stationary fluid. A mass input ($M = 0.1 \text{ g CO}_2$) is introduced instantaneously at $t = 0$ and uniformly at the center of the tube ($x = 0$). Find the time for the CO_2 to reach a concentration (mass fraction) of 1 ppm at $x = 50 \text{ cm}$ for
 - a) molecular diffusion in air
 - b) molecular diffusion in water

- 2) An infinitely long partitioned cylinder is filled with stationary pure water on the right side of the partition, and water with an initial concentration $C_0 = 10 \text{ mg/l}$ of dissolved CO_2 on the left. At time $t = 0$ the partition is removed.

- a) How long will it take the concentration of CO_2 at $x = 50 \text{ cm}$ to the right of the partition to reach 1 mg/l ?

- b) By inducing turbulence in the system it is possible to increase the diffusion coefficient. Suppose we generate homogeneous and isotropic turbulence by oscillating a grid and that the turbulent diffusion coefficient is approximately $1 \text{ cm}^2/\text{s}$. How long would it now take the concentration of CO_2 (at 50 cm from the partition) to reach 1 mg/l ?

- 3) Consider stationary fluid in an infinite cylinder of area A with a finite volume $2LA$ of dyed fluid having an initial concentration C_0 enclosed between two partitions as shown. At $t = 0$, the partitions are removed. Express the concentration of dyed fluid at an arbitrary point x as a function of time and the molecular diffusivity.
