

# 6.045: Automata, Computability, and Complexity Or, GITCS

Class 12  
Nancy Lynch

# Today: Complexity Theory

- **First part of the course: Basic models of computation**
  - Circuits, decision trees
  - DFAs, NFAs:
    - Restricted notion of computation: no auxiliary memory, just one pass over input.
    - Yields restricted class of languages: regular languages.
- **Second part: Computability**
  - Very general notion of computation.
  - Machine models like Turing machines, or programs in general (idealized) programming languages.
  - Unlimited storage, multiple passes over input, compute arbitrarily long, possibly never halt.
  - Yields large language classes: Turing-recognizable = enumerable, and Turing-decidable.
- **Third part: Complexity theory**

# Complexity Theory

- First part of the course: Basic models of computation
- Second part: Computability
- **Third part: Complexity theory**
  - A middle ground.
  - Restrict the general TM model by limiting its use of resources:
    - Computing time (number of steps).
    - Space = storage (number of tape squares used).
  - Leads to interesting subclasses of the Turing-decidable languages, based on specific bounds on amounts of resources used.
  - Compare:
    - Computability theory answers the question “What languages are computable (at all)?”
    - Complexity theory answers “What languages are computable with particular restrictions on amount of resources?”

# Complexity Theory

- **Topics**

- Examples of time complexity analysis (informal).
- Asymptotic function notation:  $O$ ,  $o$ ,  $\Omega$ ,  $\Theta$
- Time complexity classes
- $P$ , polynomial time
- Languages not in  $P$
- Hierarchy theorems

- **Reading:**

- Sipser, Sections 7.1, 7.2, and a bit from 9.1.

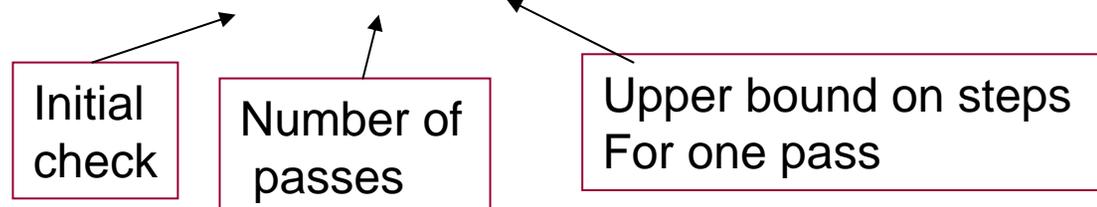

- **Next:**

- Midterm, then Section 7.3 (after the break).

# Examples of time complexity analysis

# Examples of time complexity analysis

- Consider a basic 1-tape Turing machine  $M$  that decides membership in the language  $L = \{0^k 1^k \mid k \geq 0\}$ :
  - $M$  first checks that its input is in  $0^* 1^*$ , using one left-to-right pass.
  - Returns to the beginning (left).
  - Then does repeated passes, each time crossing off one 0 and one 1, until it runs out of at least one of them.
  - If it runs out of both on the same pass, accepts, else rejects.
- **Q:** How much time until  $M$  halts?
- Depends on the particular input.
- **Example:**  $0111\dots 1110$  (length  $n$ )
  - Approximately  $n$  steps to reject---not in  $0^* 1^*$ ,
- **Example:**  $00\dots 011\dots 1$  ( $n/2$  0s and  $n/2$  1s)
  - Approximately (at most)  $2n + (n/2) 2n = 2n + n^2$  steps to accept.

# Time complexity analysis

- $L(M) = \{0^k1^k \mid k \geq 0\}$ .
- Time until  $M$  halts depends on the particular input.
- $0111\dots1110$  (length  $n$ )
  - Approximately  $n$  steps to reject---not in  $0^*1^*$ ,
- $00\dots011\dots1$  ( $n/2$  0s and  $n/2$  1s)
  - Approximately (at most)  $2n + n^2$  steps to accept.
- **It's too complicated to determine exactly how many steps are required for every input.**
- So instead, we:
  - Get a close upper bound, not an exact step count.
  - Express the bound as a function of the input length  $n$ , thus grouping together all inputs of the same length and considering the max.
  - Often ignore constant factors and low-order terms.
- So, we describe the time complexity of  $M$  as  **$O(n^2)$** .
  - At most some constant times  $n^2$ .

# Time complexity analysis

- $L(M) = \{0^k1^k \mid k \geq 0\}$ .
- Time complexity of machine  $M = O(n^2)$ .
- Q: Can we do better with a multitape machine?
- Yes, with 2 tapes:
  - After checking  $0^*1^*$ , the machine copies the 0s to the second tape.
  - Then moves 2 heads together, one scanning the 0s on the second tape and one scanning the 1s on the first tape.
  - Check that all the symbols match.
  - Time  $O(n)$ , proportional to  $n$ .

# Time complexity analysis

- $L(M) = \{0^k1^k \mid k \geq 0\}$ .
- 1-tape machine:  $O(n^2)$ , 2-tape machine:  $O(n)$ .
- Q: Can we beat  $O(n^2)$  with a 1-tape machine?
- Yes, can get  $O(n \log n)$ :
  - First check  $0^*1^*$ , as before,  $O(n)$  steps.
  - Then perform **marking** phases, as long as some unmarked 0 and some unmarked 1 remain.
  - In each marking phase:
    - Scan to see whether # of unmarked 0s  $\equiv$  # of unmarked 1s, mod 2.
      - That is, see whether they have the same parity.
    - If not, then reject, else continue.
    - Scan again, marking every other 0 starting with the first and every other 1 starting with the first.
  - After all phases are complete:
    - If just 0s or just 1s remain, then reject
    - If no unmarked symbols remain, then accept.

# Time complexity analysis

- $O(n \log n)$  algorithm:
  - Check  $0^*1^*$ .
  - Perform **marking** phases, as long as some unmarked 0 and some unmarked 1 remain.
  - In each marking phase:
    - Scan to see if # of unmarked 0s  $\equiv$  # of unmarked 1s, mod 2; if not, then reject, else continue.
    - Scan again, marking every other 0 starting with the first and every other 1 starting with the first.
  - If just 0s or just 1s remain, then reject, else accept.
- **Example:  $00\dots011\dots1$  (25 0s and 25 1s)**
  - Correct form,  $0^*1^*$ .
  - Phase 1: Same parity (odd), marking leaves 12 0s and 12 1s.
  - Phase 2: Same parity (even), marking leaves 6, 6.
  - Phase 3: Same parity (even), marking leaves 3, 3.
  - Phase 4: Same parity (odd), marking leaves 1, 1.
  - Phase 5: Same parity (odd), marking leaves 0, 0
  - Accept

# Time complexity analysis

- **Example: 00...011...1** (25 0s and 25 1s)
  - Correct form,  $0^*1^*$ .
  - Phase 1: Same parity (odd), marking leaves 12 0s and 12 1s.
  - Phase 2: Same parity (even), marking leaves 6, 6.
  - Phase 3: Same parity (even), marking leaves 3, 3.
  - Phase 4: Same parity (odd), marking leaves 1,1.
  - Phase 5: Same parity (odd), marking leaves 0,0
  - Accept
- Odd parity leads to remainder 1 on division by 2, even parity leads to remainder 0.
- Can read off odd-even parity designations to get binary representations of the numbers, starting with final phase for high-order bit:
  - 5: odd; 4: odd; 3: even; 2: even; 1: odd
  - Yields 1 1 0 0 1, binary representation of 25
- If the algorithm accepts, it means the 2 numbers have the same binary representation, so they are equal.

# Time complexity analysis

- **Example: 00...011...1** (17 0s and 25 1s)
  - Correct form,  $0^*1^*$ .
  - Phase 1: Same parity (odd), marking leaves 8 0s and 12 1s.
  - Phase 2: Same parity (even), marking leaves 4, 6.
  - Phase 3: Same parity (even), marking leaves 2, 3.
  - Phase 4: Different parity, reject
  - Don't complete this, so don't generate the complete binary representation of either number.

# Time complexity analysis

- Algorithm
  - Check  $0^*1^*$ .
  - Perform **marking** phases, as long as some unmarked 0 and some unmarked 1 remain.
  - In each marking phase:
    - Scan to see if # of unmarked 0s  $\equiv$  # of unmarked 1s, mod 2; if not, then reject, else continue.
    - Scan again, marking every other 0 starting with the first and every other 1 starting with the first.
  - If just 0s or just 1s remain, then reject, else accept.
- **Complexity analysis:**
  - Number of phases is  $O(\log_2 n)$ , since we (approximately) halve the number of unmarked 0s and unmarked 1s at each phase.
  - Time for each phase:  $O(n)$ .
  - Total:  $O(n \log n)$ .
- This analysis is informal; now define  $O$ , etc., more carefully and then revisit the example.

Asymptotic function notation:

$O, o, \Omega, \Theta$

# Asymptotic function notation

- **Definition:  $O$  (big- $O$ )**

- Let  $f, g$  be two functions:  $N \rightarrow \mathbb{R}^{\geq 0}$ .

- We write  $f(n) = O(g(n))$ , and say “ $f(n)$  is big- $O$  of  $g(n)$ ” if the following holds:

- There is a positive real  $c$ , and a positive integer  $n_0$ , such that  $f(n) \leq c g(n)$  for every  $n \geq n_0$ .

- That is,  $f(n)$  is bounded from above by a constant times  $g(n)$ , for all sufficiently large  $n$ .

- Often used for complexity upper bounds.

- **Example:**  $n + 2 = O(n)$ ; can use  $c = 2$ ,  $n_0 = 2$ .

- **Example:**  $3n^2 + n = O(n^2)$ ; can use  $c = 4$ ,  $n_0 = 1$ .

- **Example:** Any degree- $k$  polynomial with nonnegative coefficients,  $p(n) = a_k n^k + a_{k-1} n^{k-1} + \dots + a_1 n + a_0 = O(n^k)$

- Thus,  $3n^4 + 6n^2 + 17 = O(n^4)$ .

# More big-O examples

- Definition:
  - Let  $f, g: \mathbb{N} \rightarrow \mathbb{R}^{\geq 0}$
  - $f(n) = O(g(n))$  means that there is a positive real  $c$ , and a positive integer  $n_0$ , such that  $f(n) \leq c g(n)$  for every  $n \geq n_0$ .
- Example:  $3n^4 = O(n^7)$ , though this is not the tightest possible statement.
- Example:  $3n^7 \neq O(n^4)$ .
- Example:  $\log_2(n) = O(\log_e(n))$ ;  $\log_a(n) = O(\log_b(n))$  for any  $a$  and  $b$ 
  - Because logs to different bases differ by a constant factor.
- Example:  $2^{3+n} = O(2^n)$ , because  $2^{3+n} = 8 \times 2^n$
- Example:  $3^n \neq O(2^n)$

# Other notation

- **Definition:  $\Omega$  (big-Omega)**
  - Let  $f, g$  be two functions:  $\mathbb{N} \rightarrow \mathbb{R}^{\geq 0}$
  - We write  $f(n) = \Omega(g(n))$ , and say “ $f(n)$  is big-Omega of  $g(n)$ ” if the following holds:
    - There is a positive real  $c$ , and a positive integer  $n_0$ , such that  $f(n) \geq c g(n)$  for every  $n \geq n_0$ .
    - That is,  $f(n)$  is bounded from below by a positive constant times  $g(n)$ , for all sufficiently large  $n$ .
- Used for complexity lower bounds.
- **Example:**  $3n^2 + 4n \log(n) = \Omega(n^2)$
- **Example:**  $3n^7 = \Omega(n^4)$ .
- **Example:**  $\log_e(n) = \Omega(\log_2(n))$
- **Example:**  $3^n = \Omega(2^n)$

# Other notation

- **Definition:  $\Theta$  (Theta)**
  - Let  $f, g$  be two functions:  $\mathbb{N} \rightarrow \mathbb{R}^{\geq 0}$
  - We write  $f(n) = \Theta(g(n))$ , and say “ $f(n)$  is Theta of  $g(n)$ ” if  $f(n) = O(g(n))$  and  $f(n) = \Omega(g(n))$ .
  - Equivalently, there exist positive reals  $c_1, c_2$ , and positive integer  $n_0$  such that  $c_1g(n) \leq f(n) \leq c_2g(n)$  for every  $n \geq n_0$ .
- **Example:**  $3n^2 + 4n \log(n) = \Theta(n^2)$
- **Example:**  $3n^4 = \Theta(n^4)$ .
- **Example:**  $3n^7 \neq \Theta(n^4)$ .
- **Example:**  $\log_e(n) = \Theta(\log_2(n))$
- **Example:**  $3^n \neq \Theta(2^n)$

# Plugging asymptotics into formulas

- Sometimes we write things like  $2^{\Theta(\log_2 n)}$
- What does this mean?
- Means the exponent is some function  $f(n)$  that is  $\Theta(\log n)$ , that is,  $c_1 \log(n) \leq f(n) \leq c_2 \log(n)$  for every  $n \geq n_0$ .
- So  $2^{c_1 \log(n)} \leq 2^{\Theta(\log_2 n)} \leq 2^{c_2 \log(n)}$
- In other words,  $n^{c_1} \leq 2^{\Theta(\log_2 n)} \leq n^{c_2}$
- Same as  $n^{\Theta(1)}$ .

# Other notation

- **Definition:  $o$  (Little-o)**
  - Let  $f, g$  be two functions:  $\mathbb{N} \rightarrow \mathbb{R}^{\geq 0}$
  - We write  $f(n) = o(g(n))$ , and say “ $f(n)$  is little-o of  $g(n)$ ” if **for every positive real  $c$ , there is some positive integer  $n_0$ , such that  $f(n) < c g(n)$  for every  $n \geq n_0$ .**
  - In other words, no matter what constant  $c$  we choose, for sufficiently large  $n$ ,  $f(n)$  is less than  $g(n)$ .
  - In other words,  $f(n)$  grows at a slower rate than any constant times  $g(n)$ .
  - In other words,  $\lim_{n \rightarrow \infty} f(n)/g(n) = 0$ .
- **Example:**  $3n^4 = o(n^7)$
- **Example:**  $\sqrt{n} = o(n)$
- **Example:**  $n \log n = o(n^2)$
- **Example:**  $2^n = o(3^n)$

# Back to the TM running times...

- Running times (worst case over all inputs of the same length  $n$ ) of the 3 TMs described earlier:
  - Simple 1-tape algorithm:  $\Theta(n^2)$
  - 2-tape algorithm:  $\Theta(n)$
  - More clever 1-tape algorithm:  $\Theta(n \log n)$
- More precisely, consider any Turing machine  $M$  that decides a language.
- Define the running time function  $t_M(n)$  to be:
  - $\max_{w \in \Sigma^n} t'_M(w)$ , where
  - $t'_M(w)$  is the exact running time (number of steps) of  $M$  on input  $w$ .
- Then for these three machines,  $t_M(n)$  is  $\Theta(n^2)$ ,  $\Theta(n)$ , and  $\Theta(n \log n)$ , respectively.

# Time Complexity Classes

# Time Complexity Classes

- Classify decidable languages according to upper bounds on the running time for TMs that decide them.
- **Definition:** Let  $t: \mathbb{N} \rightarrow \mathbb{R}^{\geq 0}$  be a (total) function. Then  $\text{TIME}(t(n))$  is the set of languages:  
 $\{ L \mid L \text{ is decided by some } O(t(n))\text{-time Turing machine } \}$
- Call this a “time-bounded complexity class”.
- **Notes:**
  - Notice the  $O$ ---allows some slack.
  - To be careful, we need to specify which kind of TM model we are talking about; assume basic 1-tape.
- **Complexity Theory studies:**
  - Which languages are in which complexity classes.
    - E.g., is the language PRIMES in  $\text{TIME}(n^5)$ ?
  - How complexity classes are related to each other.
    - E.g., is  $\text{TIME}(n^5) = \text{TIME}(n^6)$ , or are there languages that can be decided in time  $O(n^6)$  but not in time  $O(n^5)$ ?

# Time Complexity Classes

- A problem: Running times are model-dependent.
- E.g.,  $L = \{0^k1^k \mid k \geq 0\}$ :
  - On 1-tape TM, can decide in time  $O(n \log n)$ .
  - On 2-tape TM, can decide in time  $O(n)$ .
- To be definite, we'll define the complexity classes in terms of 1-tape TMs (as Sipser does); others use multi-tape, or other models like Random-Access Machines (RAMs).
- **Q:** Is this difference important?
- Only up to a point:
  - If  $L \in \text{TIME}(f(n))$  based on any “standard” machine model, then also  $L \in \text{TIME}(g(n))$ , where  $g(n) = O(p(f(n)))$  for some polynomial  $p$ , based on any other “standard” machine model.
  - Running times for  $L$  in any two standard models are polynomial-related.
- **Example:** Single-tape vs. multi-tape Turing machines

# Time Complexity Classes

- If  $L \in \text{TIME}(f(n))$  based on any “standard” machine model, then also  $L \in \text{TIME}(g(n))$ , where  $g(n) = O(p(f(n)))$  for some polynomial  $p$ , based on any other “standard” machine model.
- **Example:** 1-tape vs. multi-tape Turing machines
  - 1-tape  $\rightarrow$  multi-tape with no increase in complexity.
  - Multi-tape  $\rightarrow$  1-tape: If  $t(n) \geq n$  then every  $t(n)$ -time multi-tape TM has an equivalent  $O(t^2(n))$ -time 1-tape TM.
  - **Proof idea:**
    - 1-tape TM simulates multi-tape TM.
    - Simulates each step of multi-tape TM using 2 scans over non-blank portion of tapes, visiting all heads, making all changes.
  - **Q:** What is the time complexity of the simulating 1-tape TM? That is, how many steps does the 1-tape TM use to simulate the  $t(n)$  steps of the multi-tape machine?

# Time Complexity Classes

- **Example:** 1-tape vs. multi-tape Turing machines
  - Multi-tape  $\rightarrow$  1-tape: If  $t(n) \geq n$  then every  $t(n)$ -time multi-tape TM has an equivalent  $O(t^2(n))$ -time 1-tape TM.
  - 1-tape TM simulates multi-tape TM; simulates each step using 2 scans over non-blank portion of tapes, visiting all heads, making all changes.
  - Q: What is the time complexity of the 1-tape TM?
  - Q: How big can the non-blank portion of the multi-tape TM's tapes become?
    - Initially  $n$ , for the input.
    - In  $t(n)$  steps, no bigger than  $t(n)$ , because that's how far the heads can travel (starts at left).
  - So the number of steps by the 1-tape TM is at most:

$$t(n) \times c t(n), \text{ hence } O(t^2(n)).$$

Number of steps of multi-tape machine

Steps taken by the scans, to emulate one step of the multi-tape machine.

# Time Complexity Classes

- If  $L \in \text{TIME}(f(n))$  based on any “standard” machine model, then also  $L \in \text{TIME}(g(n))$ , where  $g(n) = O(p(f(n)))$  for some polynomial  $p$ , based on any other “standard” machine model.
- Slightly-idealized versions of real computers, programs in standard languages, other “reasonable” machine models, can be emulated by basic TMs with only polynomial increase in running time.
- Important exception: Nondeterministic Turing machines (or other nondeterministic computing models)
  - For nondeterministic TMs, running time is usually measured by max number of steps on any branch.
  - A bound of  $t(n)$  on the maximum number of steps on any branch translates into  $2^{O(t(n))}$  steps for basic deterministic TMs.

P, Polynomial Time

# P, Polynomial Time

- A formal way to define **fast computability**.
- Because of simulation results, polynomial differences are considered to be unimportant for (deterministic) TMs.
- So our definition of fast computability ignores polynomial differences.
- **Definition:** The class P of languages that are decidable in polynomial time is defined by:  
$$P = \cup_{p \text{ a poly}} \text{TIME}(p(n)) = \cup_{k \geq 0} \text{TIME}(n^k)$$
- Notes:
  - These time-bounded language classes are defined with respect to basic (1-tape, 1-head) Turing machines.
  - Simulation results imply that we could have used any “reasonable” deterministic computing model and get the same language class.
  - Robust notion.

# P, Polynomial Time

- Definition: The class P of languages that are decidable in polynomial time is defined by:
$$P = \cup_{p \text{ a poly}} \text{TIME}(p(n)) = \cup_{k \geq 0} \text{TIME}(n^k)$$
- P plays a role in complexity theory loosely analogous to that of decidable languages in computability.
- Recall Church-Turing thesis:
  - If L is decidable using some reasonable model of computation, then it is decidable using any reasonable model of computation.
- **Modified Church-Turing thesis:**
  - If L is decidable **in polynomial time** using some reasonable **deterministic** model of computation, then it is decidable **in polynomial time** using any reasonable **deterministic** model of computation.
- This is not a theorem---rather, a philosophical statement.
- Can think of this as defining what a reasonable model is.
- We'll focus on the class P for much of our work on complexity theory.

# P, Polynomial Time

- We'll focus on the class P for much of our work on complexity theory.
- **Q:** Why is P a good language class to study?
- It's **model-independent** (for reasonable models).
- It's **scalable**:
  - Constant-factor dependence on input size.
  - E.g., an input that's twice as long requires only  $c$  times as much time, for some constant  $c$  (depends on degree of the polynomial).
    - E.g., consider time bound  $n^3$ .
    - Input of length  $n$  takes time  $n^3$ .
    - Input of length  $2n$  takes time  $(2n)^3 = 8 n^3$ ,  $c = 8$ .
  - Works for all polynomials, any degree.

# P, Polynomial Time

- Q: Why is P a good language class to study?
- It's model-independent (for reasonable models).
- It's scalable.
- It has **nice composition properties**:
  - Composing two polynomials yields another polynomial.
  - This property will be useful later, when we define **polynomial-time reducibilities**.
  - Preview:  $A \leq_p B$  means that there exists a polynomial-time computable function  $f$  such that  $x \in A$  if and only if  $f(x) \in B$ .
  - Desirable theorem:  $A \leq_p B$  and  $B \in P$  imply  $A \in P$ .
  - Proof:
    - Suppose  $B$  is decidable in time  $O(n^k)$ .
    - Suppose the reducibility function  $f$  is computable in time  $O(n^l)$ .

# P, Polynomial Time

- P has **nice composition properties**:
  - $A \leq_p B$  means that there's a polynomial-time computable function  $f$  such that  $x \in A$  if and only if  $f(x) \in B$ .
  - Desirable theorem:  $A \leq_p B$  and  $B \in P$  imply  $A \in P$ .
  - Proof:
    - Suppose  $B$  is decidable in time  $O(n^k)$ , and  $f$  is computable in time  $O(n^l)$ .
    - How much time does it take to decide membership in  $A$  by reduction to  $B$ ?
    - Given  $x$  of length  $n$ , time to compute  $f(x)$  is  $O(n^l)$ .
    - Moreover,  $|f(x)| = O(n^l)$ , since there's not enough time to generate a bigger result.
    - Now run  $B$ 's decision procedure on  $f(x)$ .
    - Takes time  $O(|f(x)|^k) = O((n^l)^k) = O(n^{lk})$ .
    - Another polynomial, so  $A$  is decidable in poly time, so  $A \in P$

# P, Polynomial Time

- Q: Why is P a good language class to study?
  - It's model-independent (for reasonable models).
  - It's scalable.
  - It has nice composition properties.
- Q: What are some limitations?
  - Includes too much:
    - Allows polynomials with arbitrarily large exponents and coefficients.
    - Time  $10,000,000 n^{10,000,000}$  isn't really feasible.
    - In practice, running times are usually low degree polynomials, up to about  $O(n^4)$ .
    - On the other hand, proving a non-polynomial lower bound is likely to be meaningful.

# P, Polynomial Time

- Q: Why is P a good language class to study?
  - It's model-independent (for reasonable models).
  - It's scalable.
  - It has nice composition properties.
- Q: What are some limitations?
  - Includes too much.
  - Excludes some things:
    - Considers **worst case time complexity** only.
      - Some algorithms may work well enough in most cases, or in common cases, even though the worst case is exponential.
    - **Random choices**, with membership being decided with high probability rather than with certainty.
    - **Quantum computing**.

# P, Polynomial Time

- **Example:** A language in P.
  - $\text{PATH} = \{ \langle G, s, t \rangle \mid G = (V, E) \text{ is a digraph that has a directed path from } s \text{ to } t \}$
  - Represent  $G$  by adjacency matrix ( $|V|$  rows and  $|V|$  columns, 1 indicates an edge, 0 indicates no edge).
  - **Brute-force algorithm:** Try all paths of length  $\leq |V|$ .
    - Exponential running time in input size, not polynomial.
  - **Better algorithm:** BFS of  $G$  starting from  $s$ .
    - Mark new nodes accessible from already-marked nodes, until no new nodes are found.
    - Then see if  $t$  is marked.
    - Complexity analysis:
      - At most  $|V|$  phases are executed.
      - Each phase takes polynomial time to explore marked nodes and their outgoing edges.

A Language Not in P

# A Language Not in P

- **Q:** Is every language in P?
- No, because  $P \subseteq$  decidable languages, and not every language is decidable.
- **Q:** Is every decidable language in P?
- No again, but it takes some work to show this.
- **Theorem:** For any computable function  $t$ , there is a language that is decidable, but cannot be decided by any basic Turing machine in time  $t(n)$ .
- **Proof:**
  - Fix computable function  $t$ .
  - Define language  $\text{Acc}(t)$   
 $= \{ \langle M \rangle \mid M \text{ is a basic TM and } M \text{ accepts } \langle M \rangle \text{ in } \leq t(|\langle M \rangle|) \text{ steps} \}$ .
  - **Claim 1:**  $\text{Acc}(t)$  is decidable.
  - **Claim 2:**  $\text{Acc}(t)$  is not decided by any basic TM in  $\leq t(n)$  steps.

# A Language Not in P

- **Theorem:** For any computable function  $t$ , there is a language that is decidable, but cannot be decided by any basic Turing machine in time  $t(n)$ .
- **Proof:**
  - $\text{Acc}(t) = \{ \langle M \rangle \mid M \text{ is a basic TM that accepts } \langle M \rangle \text{ in } \leq t(|\langle M \rangle|) \text{ steps} \}$ .
  - **Claim 1:**  $\text{Acc}(t)$  is decidable.
    - Given  $\langle M \rangle$ , simulate  $M$  on  $\langle M \rangle$  for  $t(|\langle M \rangle|)$  simulated steps and see if it accepts.
  - **Claim 2:**  $\text{Acc}(t)$  is not decided by any basic TM in  $\leq t(n)$  steps.
    - Use a diagonalization proof, like that for  $\text{Acc}_{\text{TM}}$ .
    - Assume  $\text{Acc}(t)$  is decided in time  $\leq t(n)$  by some basic TM.
      - Here,  $n = |\langle M \rangle|$  for input  $\langle M \rangle$ .

# A Language Not in P

- **Theorem:** For any computable function  $t$ , there is a language that is decidable, but cannot be decided by any basic Turing machine in time  $t(n)$ .
- $\text{Acc}(t) = \{ \langle M \rangle \mid M \text{ is a basic TM that accepts } \langle M \rangle \text{ in } \leq t(|\langle M \rangle|) \text{ steps} \}$ .
- **Claim 2:**  $\text{Acc}(t)$  is not decided by any basic TM in  $\leq t(n)$  steps.
- **Proof:**
  - Assume  $\text{Acc}(t)$  is decided in time  $\leq t(n)$  by some basic TM.
  - Then  $\text{Acc}(t)^c$  is decided in time  $\leq t(n)$ , by another basic TM.
    - Interchange  $q_{\text{acc}}$  and  $q_{\text{rej}}$  states.
  - Let  $M_0$  be a basic TM that decides  $\text{Acc}(t)^c$  in time  $\leq t(n)$ .
    - That means  $t(n)$  steps of  $M_0$ , not  $t(n)$  simulated steps.
  - Thus, for every basic Turing machine  $M$ :
    - If  $\langle M \rangle \in \text{Acc}(t)^c$ , then  $M_0$  accepts  $\langle M \rangle$  in time  $\leq t(|\langle M \rangle|)$ .
    - If  $\langle M \rangle \in \text{Acc}(t)$ , then  $M_0$  rejects  $\langle M \rangle$  in time  $\leq t(|\langle M \rangle|)$ .

# A Language Not in P

- **Theorem:** For any computable function  $t$ , there is a language that is decidable, but cannot be decided by any basic Turing machine in time  $t(n)$ .
- $\text{Acc}(t) = \{ \langle M \rangle \mid M \text{ is a basic TM that accepts } \langle M \rangle \text{ in } \leq t(|\langle M \rangle|) \text{ steps} \}$ .
- **Claim 2:**  $\text{Acc}(t)$  is not decided by any basic TM in  $\leq t(n)$  steps.
- **Proof:**
  - Assume  $\text{Acc}(t)$  is decided in time  $\leq t(n)$  by some basic TM.
  - $\text{Acc}(t)^c$  is decided in time  $\leq t(n)$ , by basic TM  $M_0$ .
  - Thus, for every basic Turing machine  $M$ :
    - If  $\langle M \rangle \in \text{Acc}(t)^c$ , then  $M_0$  accepts  $\langle M \rangle$  in time  $\leq t(|\langle M \rangle|)$ .
    - If  $\langle M \rangle \in \text{Acc}(t)$ , then  $M_0$  rejects  $\langle M \rangle$  in time  $\leq t(|\langle M \rangle|)$ .
  - Thus, for every basic Turing machine  $M$ :
    - $\langle M \rangle \in \text{Acc}(t)^c$  iff  $M_0$  accepts  $\langle M \rangle$  in time  $\leq t(|\langle M \rangle|)$ .

# A Language Not in P

- **Theorem:** For any computable function  $t$ , there is a language that is decidable, but cannot be decided by any basic Turing machine in time  $t(n)$ .
- $\text{Acc}(t) = \{ \langle M \rangle \mid M \text{ is a basic TM that accepts } \langle M \rangle \text{ in } \leq t(|\langle M \rangle|) \text{ steps} \}$ .
- **Claim 2:**  $\text{Acc}(t)$  is not decided by any basic TM in  $\leq t(n)$  steps.
- **Proof:**
  - Assume  $\text{Acc}(t)$  is decided in time  $\leq t(n)$  by some basic TM.
  - $\text{Acc}(t)^c$  is decided in time  $\leq t(n)$ , by basic TM  $M_0$ .
  - For every basic Turing machine  $M$ :
    - $\langle M \rangle \in \text{Acc}(t)^c$  iff  $M_0$  accepts  $\langle M \rangle$  in time  $\leq t(|\langle M \rangle|)$ .
  - However, by definition of  $\text{Acc}(t)$ , for every basic TM  $M$ :
    - $\langle M \rangle \in \text{Acc}(t)^c$  iff  $M$  does not accept  $\langle M \rangle$  in time  $\leq t(|\langle M \rangle|)$ .

# A Language Not in P

- **Claim 2:**  $\text{Acc}(t)$  is not decided by any basic TM in  $\leq t(n)$  steps.
- **Proof:**
  - Assume  $\text{Acc}(t)$  is decided in time  $\leq t(n)$  by some basic TM.
  - $\text{Acc}(t)^c$  is decided in time  $\leq t(n)$ , by basic TM  $M_0$ .
  - For every basic Turing machine  $M$ :
    - $\langle M \rangle \in \text{Acc}(t)^c$  iff  $M_0$  accepts  $\langle M \rangle$  in time  $\leq t(|\langle M \rangle|)$ .
    - $\langle M \rangle \in \text{Acc}(t)^c$  iff  $M$  does not accept  $\langle M \rangle$  in time  $\leq t(|\langle M \rangle|)$ .
  - Now plug in  $M_0$  for  $M$  in both statements:
    - $\langle M_0 \rangle \in \text{Acc}(t)^c$  iff  $M_0$  accepts  $\langle M_0 \rangle$  in time  $\leq t(|\langle M_0 \rangle|)$ .
    - $\langle M_0 \rangle \in \text{Acc}(t)^c$  iff  $M_0$  does not accept  $\langle M_0 \rangle$  in time  $\leq t(|\langle M_0 \rangle|)$ .
  - Contradiction!

# A Language Not in P

- $\text{Acc}(t) = \{ \langle M \rangle \mid M \text{ is a basic TM that accepts } \langle M \rangle \text{ in } \leq t(|\langle M \rangle|) \text{ steps} \}$ .
- We have proved:
- Theorem: For any computable function  $t$ , there is a language that is decidable, but cannot be decided by any basic Turing machine in time  $t(n)$ .
- Proof:
  - Claim 1:  $\text{Acc}(t)$  is decidable.
  - Claim 2:  $\text{Acc}(t)$  is not decided by any basic TM in  $\leq t(n)$  steps.
- Thus, for every computable function  $t(n)$ , no matter how large (exponential, double-exponential,...), there are decidable languages not decidable in time  $t(n)$ .
- In particular, there are decidable languages not in P.

# Hierarchy Theorems

# Hierarchy Theorems

- Simplified summary, from Sipser Section 9.1.
- $\text{Acc}(t) = \{ \langle M \rangle \mid M \text{ is a basic TM that accepts } \langle M \rangle \text{ in } \leq t(|\langle M \rangle|) \text{ steps} \}$
- We have just proved that, for any computable function  $t$ , the language  $\text{Acc}(t)$  is decidable, but cannot be decided by any basic TM in time  $t(n)$ .
- **Q:** How much time does it take to compute  $\text{Acc}(t)$ ?
- More than  $t(n)$ , but how much more?
- Technical assumption:  $t$  is “time-constructible”, meaning it can be computed in an amount of time that is not much bigger than  $t$  itself.
  - Examples: Typical functions, like polynomials, exponentials, double-exponentials,...

# Hierarchy Theorems

- $\text{Acc}(t) = \{ \langle M \rangle \mid M \text{ is a basic TM that accepts } \langle M \rangle \text{ in } \leq t(|\langle M \rangle|) \text{ steps} \}$
- **Q:** How much time does it take to compute  $\text{Acc}(t)$ ?
- **Theorem (informal statement):** If  $t$  is any time-constructible function, then  $\text{Acc}(t)$  can be decided by a basic TM in time not much bigger than  $t(n)$ .
  - E.g., approximately  $t^2(n)$ .
  - Sipser (Theorem 9.10) gives a tighter bound.
- **Q:** Why exactly does it take much more than  $t(n)$  time to run an arbitrary machine  $M$  on  $\langle M \rangle$  for  $t(|\langle M \rangle|)$  simulated steps?
- We must simulate an arbitrary machine  $M$  using a fixed “universal” TM, with a fixed state set, fixed alphabet, etc.

# Hierarchy Theorems

- **Theorem (informal):** If  $t$  is any time-constructible function, then  $\text{Acc}(t)$  can be decided by a basic TM in time not much bigger than  $t(n)$ .
  - E.g., approximately  $t^2(n)$ .
- Implies that there is:
  - A language decidable in time  $n^2$  but not time  $n$ .
  - A language decidable in time  $n^6$  but not time  $n^3$ .
  - A language decidable in time  $4^n$  but not time  $2^n$ .
- Extend this reasoning to show:
  - $\text{TIME}(n) \neq \text{TIME}(n^2) \neq \text{TIME}(n^4) \dots$   
 $\neq \text{TIME}(2^n) \neq \text{TIME}(4^n) \dots$
- A hierarchy of distinct language classes.
