**Problem 1.14**

*This problem is from “Advanced Fluid Mechanics Problems” by A.H. Shapiro and A.A. Sonin*

*Cylinder with Liquid Rotating*

- (a) Demonstrate that when a cylindrical can of liquid rotates like a solid body about its vertical axis with uniform angular velocity,  $\omega$ , the free surface is a parabolic of revolution.
- (b) Demonstrate that the pressure difference between any two points in the fluid is given by

$$p_2 - p_1 = \rho g(z_2 - z_1) + \rho \omega^2(r_2^2 - r_1^2)/2, \quad (1.14a)$$

where  $z$  is elevation and  $r$  is the radial distance from the axis.

- (c) How would the results differ if the can were of square cross section?

**Solution:**

- (a) If the fluid rotates like a solid body, then

$$a_r = \frac{V_{\theta}^2}{r} = \omega^2 r, \quad (1.14b)$$

then, for the fluid

$$\frac{\partial p}{\partial r} = \rho \omega^2 r, \quad (1.14c)$$

and now, considering gravity,

$$\frac{\partial p}{\partial z} = -\rho g. \quad (1.14d)$$

At the surface,  $\Delta p = 0$ , then  $\frac{\partial p}{\partial r_s} \delta r_s + \frac{\partial p}{\partial z_s} \delta z_s = 0$ , or  $\rho \omega^2 r_s \delta r_s - \rho g \delta z_s = 0$ , then

$$\omega^2 r_s \delta r_s = g \delta z_s, \Rightarrow \int \omega^2 r_s \delta r_s = \int g \delta z_s, \Rightarrow z_s = \frac{\omega^2 r_s^2}{2g} + Const, \quad (1.14e)$$

then the surface is a revolution paraboloid.

- (b) Now, let's integrate the radial derivative and differentiate with respect to the axial coordinate to compare the equations,

$$\frac{\partial p}{\partial r} = \rho \omega^2 r, \Rightarrow p(r, z) = \rho \omega^2 \frac{r^2}{2} + f(z), \Rightarrow \frac{\partial p}{\partial z} = \frac{\partial f}{\partial z}, \quad (1.14f)$$

Now, comparing both expressions for  $\frac{\partial p}{\partial z}$ , we notice that  $\rho g = \frac{\partial f}{\partial z}$ , then  $f = -\rho g z + Const$ . Finally,

$$p(z, r) = \rho \omega^2 \frac{r^2}{2} - \rho g z + Const, \quad (1.14g)$$

then, for two different points inside the liquid,

$$p(z_2, r_2) - p(z_1, r_1) = \rho \omega^2 \left( \frac{r_2^2}{2} - \frac{r_1^2}{2} \right) - \rho g (z_2 - z_1), \quad (1.14h)$$

- (c) No practical difference, the surface just would be cut by two planes instead of a cylinder (the effects of surface tension would be different, but this is unimportant as long as the surface tension contribution is small).
