

12.4 Problem Set 4 Solutions

1. A nice derivation on the theoretical lower bound on Higgs mass (note experimental lower bound is $\mu_H \geq 120\text{GeV}$ by now) can be found in G. Attarelli, G. Isideri, Phys. Lett. B337 p141 ('94) (available on the SPIRES). This uses two-loop corrections and the result for ($\mu_t \simeq 174\text{GeV}$) as a function of cut-off scale Λ is as follows:

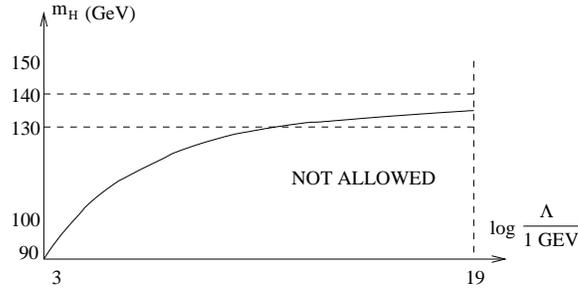

Figure 12.41: Lower Bound.

I will sketch the argument, see the paper for details.

Tree level Higgs potential is

$$V_{tree} = -\frac{\mu_0 \emptyset^2}{2} + \frac{\lambda_0 \emptyset^4}{24} \quad (12.164)$$

where we fix λ_0 and μ_0 at renormalization scale $\mu_0 = \mu = v \simeq 245\text{GeV}$ (at weak scale).

As $\mu \rightarrow \mu + \delta\mu$, Higgs field strength scales as $\emptyset \rightarrow \emptyset(1 + \delta\eta)$ and $\lambda \rightarrow \lambda + \delta\lambda$.

Accordingly the renormalized potential is

$$V_{Ren} = \frac{1}{24} \lambda(\mu) ((1 + \delta\eta(\mu)) \emptyset)^4 \quad (12.165)$$

For one-loop corrections we can write

$$1 + \delta\eta \simeq e^{\delta\eta} = \exp\left[-\int_0^{\log \frac{\Lambda}{\mu_0}} \gamma[t'] dt'\right] \quad (12.166)$$

where

$$\gamma \equiv -\frac{\mu}{\delta\mu} \delta\eta = -\frac{\delta\eta}{\delta \log \frac{\mu}{\mu_0}} \equiv -\frac{\delta\eta}{\delta t'} \quad (12.167)$$

These one-loop effects can turn the tail of $V_{tree}(\phi)$ downwards for large ϕ hence $V_{Ren}(\phi)$ may become unstable.

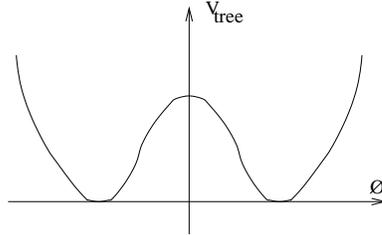

Figure 12.42: V_{tree} .

From Equation 12.165 the condition for stability is clearly

$$\lambda(\mu) > 0 \tag{12.168}$$

Thus we shall look at how λ evolves:

$$\frac{\lambda}{t} = \beta(t) = \frac{\partial}{\partial \ln \mu} (-\delta_\lambda + 2\delta_\theta) \tag{12.169}$$

where δ_λ is the counterterm for

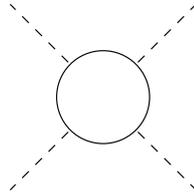

Figure 12.43: δ_λ Equation 12.169.

and δ_θ is Higgs self-renormalization

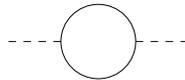

Figure 12.44: δ_θ Equation 12.169.

We just draw contributing diagrams and give the result:

take only top quark.

→ δ_λ (from log-divergent pieces)

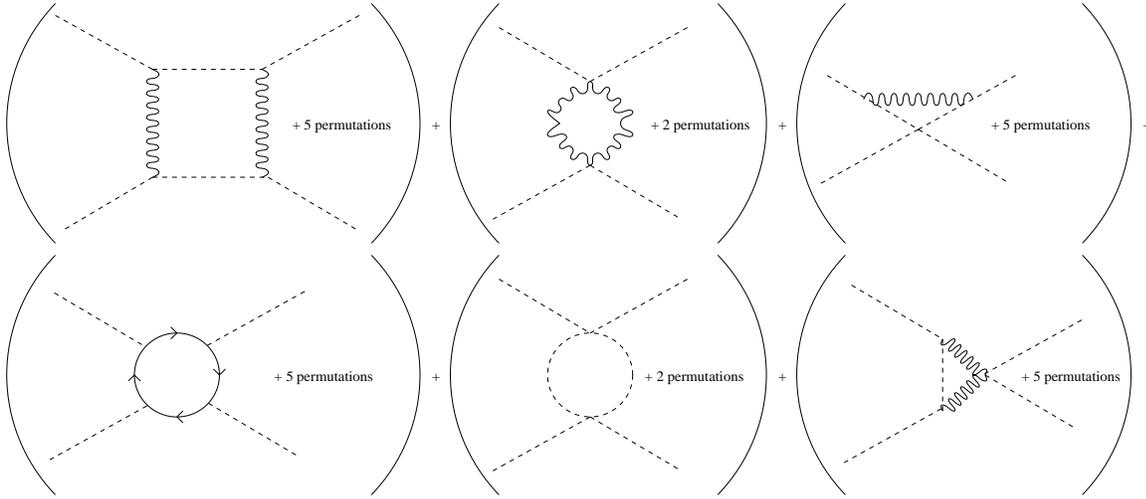

Figure 12.45: Contributing Diagrams δ_λ .

Figure 12.46: Contributing Diagrams δ_θ .

take only top.

→ δ_θ (from log-divergent pieces)

Therefore,(see above mentioned paper) for the result. Actually I will quote two-loop result:

$$\frac{d\lambda}{dt} = \frac{1}{16\pi^2} [4\lambda^2 + 12\lambda g_t^2 - 36g_t^4 - 9\lambda g_1^2 - 3\lambda g_2^2 + \frac{9}{2}g_1^2 g_2^2 + \frac{27}{4}g_1^4] \quad (12.170)$$

where g_t is the Yukawa coupling for top quark, g_1 and g_2 are $U(1)_Y$ and $SU(2)_W$ coupling.

We have

$$g_t(\mu_0) = \frac{\sqrt{2}m_t}{V}(a + \delta_t(\mu_0)) \quad (12.171)$$

$$\lambda_t(\mu_0) = \frac{3m_H^2}{V^2}(a + \delta_\lambda(\mu_0)) \quad (12.172)$$

at $\mu_0 = \text{weak scale} \simeq 100\text{GeV}$. (note that the funny factors of 3 in $\frac{\lambda}{m_H^2}$ is coming from my unusual V_{tree} definition).

Therefore, we see that λ can become negative, hence V_{Ren} unstable for particular values of Λ , m_t^2 and m_H^2 . To find the range of m_H^2 for which $\lambda > 0$ fix $m_t^2 \simeq 174\text{GeV}$ (ignore QCD corrections). Then solve the above equation for $\frac{d\lambda}{dt}$ numerically and the one gets the range as shown in Figure 12.41.

2. Consider

$$L[\phi] = \frac{1}{2}\partial_\mu\phi\partial^\mu\phi - V(\phi) \quad (12.173)$$

Suppose we expand around $\langle \phi \rangle = v(x)$ where $V(\phi)$ looks like

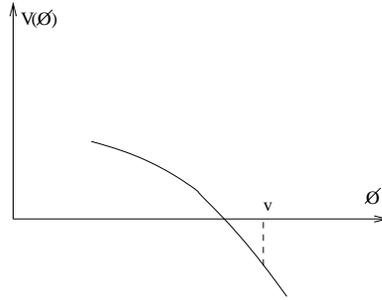

Figure 12.47: $V(\phi)$.

For simplicity lets take

$$V(\phi) \simeq \omega\phi^2 + C \quad (12.174)$$

with $\omega < 0$.

The ground state is a coherent state such that, for

$$\phi(\vec{x}) = \int \frac{d^3k}{(2\pi)^3} \frac{1}{\sqrt{2k_0}} (a_k e^{i\vec{k}\cdot\vec{x}} + a_k^+ e^{-i\vec{k}\cdot\vec{x}}) = \hat{\phi}_+ + \hat{\phi}_- \quad (12.175)$$

$$\hat{\phi}_+(\vec{x})|\xi\rangle = \int \frac{d^3k}{(2\pi)^3} \frac{1}{\sqrt{2k_0}} \xi(k) e^{i\vec{k}\cdot\vec{x}} |\xi\rangle \quad (12.176)$$

Lets consider a 0 + 1 dimensional system for simplicity:

$$\hat{H} = \omega[a^\dagger a + \frac{1}{2}] \quad (12.177)$$

$$\langle \xi | H | \xi \rangle = ? \quad (12.178)$$

Solution to equation $a|\xi\rangle = \xi|\xi\rangle$ is $|\xi\rangle = e^{\xi a^\dagger}|0\rangle$ in this case

$$\langle \xi | H | \xi \rangle = \omega \langle 0 | e^{\xi a} (a^\dagger a + \frac{1}{2}) e^{\xi a^\dagger} | 0 \rangle = \omega (\xi^2 + \frac{1}{2}) e^{\xi^2} \quad (12.179)$$

Consider an excitation:

$$\langle \xi | a H a^\dagger | \xi \rangle = \frac{d}{d\xi} \frac{d}{d\xi'} \langle \xi' | H | \xi \rangle \Big|_{\xi=\xi'} = \frac{d}{d\xi} \frac{d}{d\xi'} (\xi \xi' + \frac{1}{2}) e^{\xi \xi'} \omega > \langle \xi | H | \xi \rangle \quad (12.180)$$

Excitation get lower and lower energy (straightforward) since $\omega < 0$ (for classical unstable potential).

This reasoning is easily generalized to more non-trivial potentials which exhibit non-stable behavior classically and to 4D QFT, in which case

$$|\xi\rangle = \exp\left[\int \frac{d^3k}{(2\pi)^3} \frac{1}{\sqrt{2k_0}} \xi(k) e^{i\vec{k}\cdot\vec{x}} a_k^\dagger\right] |0\rangle \quad (12.181)$$

3. (Thanks to Guide Festuccier) Observed value of

$$\frac{m_b}{m_\tau} \Big|_{\mu=\mu_z} \simeq 1.62 \quad (12.182)$$

Both in supersymmetric and non-supersymmetric GUTs b and τ are in the same multiplet and get the same mass through Higgs coupling, hence

$$\frac{m_b}{m_\tau} \Big|_{\mu=\mu_{GUT}} = 1 \quad (12.183)$$

To obtain the value at $\mu = \mu_z$ we should run the Yukawa couplings down to weak scale. One can ignore Yukawa couplings of other matter except top-quark:

MSSM:

$$\frac{d}{dt} \ln \lambda_t = \frac{1}{16\pi^2} [6\lambda_t^2 + \lambda_b^2 - \sum c_i g_i^2] \quad (12.184)$$

$$\frac{d}{dt} \ln \lambda_b = \frac{1}{16\pi^2} [-6\lambda_b^2 + \lambda_\tau^2 - \sum c'_i g_i^2] \quad (12.185)$$

$$\frac{d}{d\tau} \ln \lambda_t = \frac{1}{16\pi^2} [6\lambda_\tau^2 - 3\lambda_b^2 - \sum c''_i g_i^2] \quad (12.186)$$

$$t = \ln\left(\frac{\mu}{\mu_z}\right) \quad (12.187)$$

where g_i are ($U(1)$, $SU(2)$, and $SU(3)$) coupling for $i = 1, 2, 3$ respectively and the coefficients are:

MSSM:

$$c_i = \left(\frac{13}{5}, 3, \frac{16}{3}\right) \quad (12.188)$$

$$c'_i = \left(\frac{7}{15}, 3, \frac{16}{3}\right) \quad (12.189)$$

$$c''_i = \left(\frac{9}{5}, 3, 0\right) \quad (12.190)$$

SM:

$$c_i = \left(\frac{17}{20}, \frac{9}{4}, 8\right) \quad (12.191)$$

$$c'_i = \left(\frac{1}{4}, \frac{9}{4}, 8\right) \quad (12.192)$$

$$c''_i = \left(\frac{9}{4}, \frac{9}{4}, 0\right) \quad (12.193)$$

Subtract equations for λ_b and λ_τ and neglect λ_b with respect to λ_t to get

MSSM:

$$2\pi \frac{d}{dt} \ln\left(\frac{\lambda_b}{\lambda_\tau}\right)^2 \simeq \frac{1}{4\pi} (\lambda_t^2 - \frac{16}{3}g_3^2 + \frac{20}{15}g_1^2) \quad (12.194)$$

SM:

$$2\pi \frac{d}{dt} \ln\left(\frac{\lambda_b}{\lambda_\tau}\right)^2 \simeq \frac{1}{4\pi} (\lambda_t^2 - 8g_3^2 + 2g_1^2) \quad (12.195)$$

One straightforwardly gets

MSSM:

$$\frac{m_b}{m_\tau}(\mu_z) = \left(e^{-\frac{1}{16\pi^2} \int_0^{t(\mu_{GUT})} \lambda_t^2 dt'} \right) \left(\frac{\alpha_3(\mu_z)}{\alpha_3(\mu_{GUT})} \right)^{\frac{8}{9}} \quad (12.196)$$

(ignoring $O(g_1^2)$ with respect to $O(g_2^2)$).

SM:

$$\frac{m_b}{m_\tau}(\mu_z) = \left(e^{-\frac{1}{16\pi^2} \int_0^{t(\mu_{GUT})} \lambda_t^2 dt'} \right) \left(\frac{\alpha_3(\mu_z)}{\alpha_3(\mu_{GUT})} \right)^{\frac{4}{7}} \quad (12.197)$$

We have to obtain $\alpha_3 = \alpha_2 = \alpha_1|_{GUT}$ in MSSM vs. SM.

This is easily done by looking at one-loop running of MSSM and SM couplings and their unification at μ_{GUT} , see for instance R. Mohapatra hep-th 9801235 r2.

$$\alpha \equiv \frac{1}{(4\pi)^2} g^2 \quad (12.198)$$

$$\alpha_{GUT}^{MSSM} \simeq \frac{1}{24} \quad (12.199)$$

$$\alpha_{GUT}^{SM} \simeq \frac{1}{42} \quad (12.200)$$

One obtains

$$\frac{m_b}{m_z}(\mu_z)|_{MSSM} = \exp\left(-\frac{1}{16\pi^2} \int \lambda_t^2\right)|_{MSSM} \times 2.56 \quad (12.201)$$

$$\frac{m_b}{m_z}(\mu_z)|_{SM} = \exp\left(-\frac{1}{16\pi^2} \int \lambda_t^2\right)|_{SM} \times 2.51 \quad (12.202)$$

The difference mostly depends of the running of top-Yakawa coupling in MSSM vs. SM. According to R. H. Mohapatra, (“Supersymmetry and Unification,” Springer-Verlag, 2003) $\frac{m_b}{m_\tau} \simeq 3$ in SM which is bad as $\frac{m_b}{m_\tau} \simeq 1.62$ in reality and, $\frac{m_b}{m_\tau} \simeq 2.3$ in MSSM. But the latter result is model-dependent. Especially on the particular breaking mechanism.
