

## Chapter 11 : Multiple Linear Regression

We have:

	height	weight	...	age	amount of lemonade purchased
person 1:	$x_{11}$	$x_{12}$	$\dots$	$x_{1k}$	$y_1$
person 2:	$x_{21}$	$x_{22}$	$\dots$	$x_{2k}$	$y_2$
:					

where we assume

$$Y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \dots + \beta_k x_{ik} + \epsilon_i$$

for  $i = 1, \dots, n$  and  $\epsilon_i \sim N(0, \sigma^2)$ . The  $x_i$ 's are not random.

Is there any way we can fit something that isn't linear? Like a polynomial?

We can do least squares to find  $\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_k$ : Minimize  $Q$  where:

$$Q = \sum_i (y_i - (\beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \dots + \beta_k x_{ik}))^2.$$

Solve it the same way as we did in Chapter 10: set  $\partial Q / \partial \beta_j = 0$  for all  $j$ . In this case, we'll let the computer solve it for us. So now we have all the  $\hat{\beta}_j$ 's.

To assess the goodness of fit, again define:

$$\text{SSE} = \sum_i (y_i - \hat{y}_i)^2 \text{ where } \hat{y}_i = \hat{\beta}_0 + \hat{\beta}_1 x_{i1} + \hat{\beta}_2 x_{i2} + \dots + \hat{\beta}_k x_{ik}$$

and compare with:

$$\text{SST} = \sum_i (y_i - \bar{y})^2.$$

Again,  $\text{SSR} = \text{SST} - \text{SSE}$ .

The coefficient of "multiple" determination is :

$$r^2 = \frac{\text{SSR}}{\text{SST}} = 1 - \frac{\text{SSE}}{\text{SST}}. \tag{1}$$

This time, by convention,

$$r = +\sqrt{1 - \frac{SSE}{SST}}.$$

The square root is only positive, since it is not meaningful to assign an association between  $y$  and multiple  $x$ 's.

---

For hypothesis testing, we'll need to know:

1. Each of the coefficients obeys:

$$\hat{\beta}_j \sim N(\beta_j, \sigma^2 V_{jj})$$

where  $V_{jj}$  is the  $j$ 'th diagonal entry of  $V = (X'X)^{-1}$ ,  $j = 0, 1, \dots, k$

2. Because we don't know  $\sigma^2$ , we use

$$SE(\hat{\beta}_j) = s\sqrt{V_{jj}}$$

where  $s^2 = \frac{SSE}{n-(k+1)}$

We could do the hypothesis tests on each  $\beta_j$ :

$$\begin{aligned} H_{0j} : \beta_j &= \beta_j^0 \\ H_{1j} : \beta_j &\neq \beta_j^0. \end{aligned}$$

Reject  $H_{0j}$  when

$$|t_j| = \frac{|\hat{\beta}_j - \beta_j^0|}{SE(\hat{\beta}_j)} > t_{n-(k+1), \alpha/2}$$

and thus if  $\beta_j^0 = 0$ :

$$\begin{aligned} H_{0j} : \beta_j &= 0 \\ H_{1j} : \beta_j &\neq 0. \end{aligned}$$

Reject  $H_{0j}$  when

$$|t_j| = \frac{|\hat{\beta}_j|}{SE(\hat{\beta}_j)} > t_{n-(k+1), \alpha/2}.$$

Or we could test all  $\beta_j$ 's simultaneously:

$$H_0 : \beta_1 = \beta_2 = \dots = \beta_k = 0$$

$$H_1 : \beta_i = 0 \text{ for at least one } i.$$

Reject  $H_0$  when  $F > f_{k, n-(k+1), \alpha}$  where:

$$F = \frac{MSR}{MSE} = \frac{\frac{SSR}{k}}{\frac{SSE}{n-(k+1)}} = \frac{\frac{\sum_{i=1}^n (\hat{y}_i - \bar{y})^2}{k}}{\frac{\sum_{i=1}^n (y_i - \hat{y}_i)^2}{n-(k+1)}}.$$

Both the numerator and the denominator look like sample variances so you could see the intuition why  $\frac{MSR}{MSE}$  has an F-distribution.

Equivalently:

$$F = \frac{MSR}{MSE} = \frac{\frac{SSR}{k}}{\frac{SSE}{n-(k+1)}} \stackrel{(?)}{=} \frac{\frac{r^2 SST}{k}}{\frac{(1-r^2)SST}{n-(k+1)}} = \frac{r^2(n-k-1)}{k(1-r^2)}$$

Where did the (?) step come from?

Note: The F-test above does not tell you which  $\beta_j$ s are nonzero.

But then how do you do that?

Note: Beware of **multicollinearity**, meaning that some of the factors in the model can be determined from the others (i.e. they are linearly dependent).

Example: for savings, income, expenditure where

$$\text{savings} = \text{income} - \text{expenditure}.$$

This makes computation numerically unstable and  $\hat{\beta}_j$  are not statistically significant. To avoid this, use only income and expenditure, not savings. (Or savings and income, not expenditure, etc.)

## Corresponding ANOVA regression table

Source of variation	sum of squares	d.f.	Mean Square	$F$	p
Regression	SSR	$k$	$MSR = \frac{SSR}{k}$	$F = \frac{MSR}{MSE}$	p-value
Error	SSE	$n - (k + 1)$	$MSE = \frac{SSE}{n - (k + 1)}$		
Total	SST	$n - 1$			

We can also put the hypothesis tests for the individual  $\beta_j$ 's in a table:

predictor	SE	t-statistic	p-value
$\hat{\beta}_0$	$SE(\hat{\beta}_0)$	$t = \frac{\hat{\beta}_0}{SE(\hat{\beta}_0)}$	p-value
$\hat{\beta}_1$	$SE(\hat{\beta}_1)$	$t = \frac{\hat{\beta}_1}{SE(\hat{\beta}_1)}$	p-value
$\vdots$	$\vdots$	$\vdots$	$\vdots$
$\hat{\beta}_k$	$SE(\hat{\beta}_k)$	$t = \frac{\hat{\beta}_k}{SE(\hat{\beta}_k)}$	p-value
